Chapter One

INTRODUCTION

This document, the City of Greenfield Stormwater Technical Standards Manual, prepared by Christopher B. Burke Engineering, Ltd. for City of Greenfield, contains the necessary technical standards for administering the requirements of 327 IAC 15-13 and the City of Greenfield Stormwater Management Ordinance. This document should be considered as a companion document to the Ordinance. Whereas the Ordinance contains the majority of the regulatory authority and general requirements of comprehensive stormwater management, this document contains the necessary means and methods for achieving compliance with the Ordinance. It is not intended as a regulatory document, but rather guidance to assist plan reviewers, developers, and designers. In case there are conflicts between the requirements contained in this document and the Ordinance, the requirements of the Ordinance should prevail.

This document contains formulas and methodologies for the review and design of both stormwater quantity and stormwater quality facilities. Chapters 2 through 6 contain stormwater conveyance and detention calculations and requirements. Chapter 7 contains information on erosion control requirements and other pollution prevention measures for active construction sites. Chapters 8 through 9 cover calculations required to properly size and design stormwater quality features that will treat runoff long-term following construction completion. A comprehensive glossary of terms is provided in Appendix A. Appendix B contains several useful and necessary standard forms. Best Management Practices (BMPs) for erosion control measures during the construction phase are contained in Appendix C. Appendix D contains BMPs for post-construction erosion and sediment control measures. It is the intent of the City of Greenfield that material presented in Appendices C and D will be revised or eliminated once the Indiana Stormwater Quality Manual is published in its final form by the Indiana Department of Natural Resources (IDNR) to provide consistency.

In addition to the requirements of the City of Greenfield Stormwater Management Ordinance and this Stormwater Technical Standards Manual, adherence to other requirements contained in the City of Greenfield Public Improvement Design Standards and Greenfield Code of Ordinance is also required. When there are any discrepancies between these documents, the most restrictive shall apply.
METHODOLOGY FOR DETERMINATION OF RUNOFF RATES

Runoff rates shall be computed for the area of the parcel under development plus the area of the watershed flowing into the parcel under development. The rate of runoff which is generated as the result of a given rainfall intensity may be calculated as follows:

A. Development Sites Less than or Equal to 5 Acres in Size, With a Contributing Drainage Area Less than or Equal to 50 Acres and No Depressional Storage

The Rational Method may be used. A computer model, such as TR-55 (NRCS), TR-20 (NRCS), HEC-HMS (COE), and HEC-1 (COE), that can generate hydrographs based on the NRCS TR-55 time of concentration and curve number calculation methodologies may also be used along with a 24-hour duration NRCS Type 2 storm. Note that for the purpose of determining the post-developed conditions curve numbers, due to significant disturbance to the upper soil layers during the construction activities, the initially determined hydrologic soil group for disturbed areas should be changed to the next less infiltrating capacity category (i.e., A to B, B to C, and C to D). In the Rational Method, the peak rate of runoff, Q, in cubic feet per second (cfs) is computed as:

\[ Q = CIA \]

Where:  
\[ C = \text{Runoff coefficient, representing the characteristics of the drainage area and defined as the ratio of runoff to rainfall.} \]
\[ I = \text{Average intensity of rainfall in inches per hour for a duration equal to the time of concentration (t_c) for a selected rainfall frequency.} \]
\[ A = \text{Tributary drainage area in acres.} \]

Values for the runoff coefficient "C" are provided in Tables 2-1 and 2-2, which show values for different types of surfaces and local soil characteristics. The composite "C" value used for a given drainage area with various surface types shall be the weighted average value for the total area calculated from a breakdown...
of individual areas having different surface types. Table 2-3 provides runoff coefficients and inlet times for different land use classifications.

Rainfall intensity shall be determined from the rainfall frequency data shown in Table 2-4.

In general, the time of concentration (t_c) methodology to be used for all stormwater management projects within City of Greenfield shall be as outlined in the U.S. Department of Agriculture (USDA) - NRCS TR-55 Manual. In urban or developed areas, the methodology to be used shall be the sum of the inlet time and flow time in the stormwater facility from the most remote part of the drainage area to the point under consideration. The flow time in the storm sewers may be estimated by the distance in feet divided by velocity of flow in feet per second. The velocity shall be determined by the Manning's Equation (see Chapter 4). Inlet time is the combined time required for the runoff to reach the inlet of the storm sewer. It includes overland flow time and flow time through established surface drainage channels such as swales, ditches, and sheet flow across such areas as lawns, fields, and other graded surfaces.

(1) Flat terrain involves slopes of 0-2%.
(2) Rolling terrain involves slopes of 2-7%.
(3) Steep terrain involves slopes greater than 7%.
(4) Interpolation, extrapolation and adjustment for local conditions shall be based on engineering experience and judgment.
B. Development Sites Greater Than 5 Acres in Size or Contributing Drainage Area Greater than 50 Acres or With Significant Depressional Storage

The runoff rate for these development sites and contributing drainage areas shall be determined by a computer model that can generate hydrographs based on the NRCS TR-55 time of concentration and curve number calculation methodologies and the 24-hour NRCS Type 2 Rainfall Distribution. Note that for the purpose of determining the post-developed conditions curve numbers, due to significant disturbance to the upper soil layers during the construction activities, the initially determined hydrologic soil group for disturbed areas should be changed to the next less infiltrating capacity category (i.e., A to B, B to C, and C to D). 24-hour Rainfall depth for various frequencies shall be taken from Table 2-5. The NRCS Type 2 distribution ordinates are found in Table 2-6. Examples of computer models that can generate such hydrographs include TR-55 (NRCS), TR-20 (NRCS), HEC-HMS (COE), and HEC-1 (COE). These programs may be downloaded free of charge from the associated agencies’ web sites. The computer models ICPR and Pond Pack may also be used. However, the latter computer software are proprietary. If interconnected ponds are utilized, the use of ICPR or Pond Pack may be required to appropriately model the more complex hydrologic and hydraulic relationships associated with such system. Other models may be acceptable and must be accepted by the City Engineer prior to their utilization.

Chapter 2 – Page 7
C. Development Sites with Drainage Areas Greater than or Equal to One Square Mile

The drainage design of any major drainage system, as defined in Appendix A, must be obtained from, or be accepted by, the IDNR. Other portions of the site must use the discharge methodology in the applicable section of this Article.
### METHODOLOGY FOR DETERMINATION OF DETENTION STORAGE VOLUMES

#### A. Development Sites Less than or Equal to 5 Acres in Size, With a Contributing Drainage Area Less than or Equal to 50 Acres and No Depressional Storage

The required volume of stormwater storage may be calculated using the Rational Method and based on the runoff from a 100-year return period storm. A computer model, such as TR-55 (NRCS), TR-20 (NRCS), HEC-HMS (COE), and HEC-1 (COE), that can generate hydrographs based on the NRCS TR-55 time of concentration and curve number calculation methodologies may also be used along with a 24-hour duration NRCS Type 2 storm. Note that for the purpose of determining the post-developed conditions curve numbers, due to significant disturbance to the upper soil layers during the construction activities, the initially determined hydrologic soil group for disturbed areas should be changed to the next less infiltrating capacity category (i.e., A to B, B to C, and C to D).

The following 9-step procedure, based on the Rational Method, may be used to determine the required volume of storage:

<table>
<thead>
<tr>
<th>Step</th>
<th>Procedure</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>Determine total drainage area in acres &quot;A&quot;.</td>
</tr>
<tr>
<td>2.</td>
<td>Determine the parcel area tributary to each outlet and determine the post-development 100-year release runoff rate ( (Q_u) ) based on general release rates provided in Chapter 6 of these Technical Standards document.</td>
</tr>
<tr>
<td>3.</td>
<td>Determine composite runoff coefficient ( (C_d) ) based on developed conditions and a 100-year return period.</td>
</tr>
<tr>
<td>4.</td>
<td>Determine 100-year return rainfall intensity ( (I_d) ) for various storm durations ( (t_d) ) up through the time of concentration for the developed area using Table 2-4.</td>
</tr>
<tr>
<td>5.</td>
<td>Determine developed inflow rates ( (Q_d) ) for various storm durations ( (t_d) ), measured in hours.</td>
</tr>
<tr>
<td>( Q_d = (C_d)(I_d)(A_d) )</td>
<td></td>
</tr>
<tr>
<td>6.</td>
<td>Compute a storage rate ( (S(t_d)) ) for various storm durations ( (t_d) ) up through the time of concentration of the developed area.</td>
</tr>
</tbody>
</table>
7. Compute required storage volume "S_R" in acre-feet for each storm duration "t_d". This assumes a triangular hydrograph of duration (2t_d) hours with a peak flow of S(t_d) at t_d hours.

\[ S(t_d) = (Q_d) - (Q_e) \]

\[ S_R = S(t_d) \left( \frac{2t_d}{12} \right) \]

8. Select largest storage volume computed in Step 7 for any storm duration "t_d" for detention basin design.

9. Repeat Steps 2-8 of this process for the post-developed 10-year storm.

B. Development Sites Greater Than 5 Acres in Size or Contributing Drainage Area Greater than 50 Acres or With Significant Depressional Storage

All runoff detention storage calculations for these development sites shall be prepared using a computer model that can generate hydrographs based on the NRCS TR-55 time of concentration and curve number calculation methodologies. Note that for the purpose of determining the post-developed conditions curve numbers, due to significant disturbance to the upper soil layers during the construction activities, the initially determined hydrologic soil group for disturbed areas should be changed to the next less infiltrating capacity category (i.e., A to B, B to C, and C to D). The 24-hour NRCS Type 2 Rainfall Distribution shall be utilized to determine the required storage volume. The allowable release rates shall be determined based on the methodologies provided in Chapter 6 of this Technical Standards Manual. Examples of computer models that can generate such hydrographs include TR-55 (NRCS), TR-20 (NRCS), HEC-HMS (COE), and HEC-1 (COE). These programs may be downloaded free of charge from the associated agencies’ web sites. The computer models ICPR and Pond Pack may also be used. However, the latter computer software are proprietary. If interconnected ponds are utilized, the use of ICPR or Pond Pack may be required to appropriately model the more complex hydrologic and hydraulic relationships associated with such system. Other models may be acceptable and must be accepted by the City Engineer prior to their utilization.
All storm sewers, whether private or public, and whether constructed on private or public property shall conform to the City of Greenfield Public Improvement Design Standards as well as other requirements contained herein.

A. Design Storm Frequencies

1. All storm sewers, inlets, catch basins, and street gutters shall accommodate (subject to the “allowable spread” provisions discussed later in this Section), at a minimum, peak runoff from a 10-year return frequency storm calculated based on methodology described in Chapter 2. Additional discharges to storm sewer systems allowed in Section L below of this Section must be considered in all design calculations. If the Rational Method analysis is utilized for design, the duration shall be equal to the time of concentration for the drainage area. In computer based analysis, the duration is as noted in the applicable methodology associated with the computer program.

2. Culverts shall be capable of accommodating, without overtopping the road, peak runoff from a 50-year frequency storm when crossing under a road which is part of the City of Greenfield Thoroughfare Plan or is classified as freeway, arterial, parkway, and/or collectors by the City of Greenfield Zoning Ordinance or provides the only access to and from any portion of any commercial or residential developments.

3. The allowable spread of water on Collector Streets, for portions of the system considered minor drainage systems, is limited to maintaining two clear 10-foot moving lanes of traffic. One lane is to be maintained on local roads, while other access lanes (such as a subdivision cul-de-sac) can have a water spread equal to one-half of their total width. An overflow channel/swale between sag inlets and overflow paths or basin shall be provided at sag inlets so that the maximum depth of water that might be ponded in the street sag shall not exceed 7 inches measured from elevation of gutter.

4. Facilities functioning as a major drainage system as defined in Appendix A must also meet IDNR design standards in addition to the City of Greenfield standards. In case of discrepancy, the most restrictive requirements shall apply.
B. Manning's Equation

Determination of hydraulic capacity for storm sewers sized by the Rational Method analysis must be done using Manning's Equation. where:

\[
V = \left(\frac{1.486}{n}\right)\left(R^{2/3}\right)\left(S^{1/2}\right)
\]

Then:

\[Q = (V)(A)\]

Where:

- \(Q\) = capacity in cubic feet per second
- \(V\) = mean velocity of flow in feet per second
- \(A\) = cross sectional area in square feet
- \(R\) = hydraulic radius in feet
- \(S\) = slope of the energy grade line in feet per foot
- \(n\) = Manning's "n" or roughness coefficient

The hydraulic radius, \(R\), is defined as the cross sectional area of flow divided by the wetted flow surface or wetted perimeter. Allowable "n" values and maximum permissible velocities for storm sewer materials are listed in Table 4-1.

C. Backwater Method for Pipe System Analysis

A more sophisticated design/analysis methodology other than Manning’s equation will be required for the hydraulic analysis of existing or proposed storm drains which possess submerged outfalls. The backwater analysis method provides a more accurate estimate of pipe flow by calculating individual head losses in pipe systems that are surcharged and/or have submerged outlets. These head losses are added to a known downstream water surface elevation to give a design water surface elevation for a given flow at the desired upstream location. Total head losses may be determined as follows:

Total head loss = frictional loss + manhole/inline BMP loss + velocity head loss + junction loss

</table>

(1) New earth (uniform, sodded, clay soil)
(2) Existing earth (fairly uniform, with some weeds).
Various computer modeling programs such as HYDRA, ILLUDRAIN, and STORMCAD are available for analysis of storm drains under these conditions. Computer models to be utilized, other than those listed, must be accepted by the City Engineer.

D. Minimum Size for Storm Sewers

The minimum diameter of all storm sewers shall be 12 inches. When the minimum 12-inch diameter pipe will not limit the rate of release to the required amount, the rate of release for detention storage shall be controlled by an orifice plate or other device, subject to acceptance of the City Engineer.

E. Pipe Cover, Grade, and Separation from Sanitary Sewers

Pipe grade shall be such that, in general, a minimum of 2.0 feet of cover is maintained over the top of the pipe. If the pipe is to be placed under pavement, then the minimum pipe cover shall be 2.5 feet from top of pavement to top of pipe. Pipe cover less than the minimum may be allowed per manufacturer’s specifications or recommendation and used only upon written acceptance from the City Engineer. However, the applicant must show that such smaller cover depth would still meet gross vehicle weight rating of largest City of Greenfield Fire Department truck. Uniform slopes shall be maintained between inlets, manholes and inlets to manholes. Final grade shall be set with full consideration of the capacity required, sedimentation problems, and other design parameters. Minimum and maximum allowable slopes shall be those capable of producing velocities of between 2.5 and 10 feet per second, respectively, when the sewer is flowing full. Maximum permissible velocities for various storm sewer materials are listed in Table 4-1. A minimum of 2.0 feet of vertical separation between storm sewers and sanitary sewers shall be required. When this is not possible, A crossing method approved by the City Engineer shall be utilized.

F. Alignment

Storm sewers shall be straight between manholes, inlets, and catch basins.

G. Manholes/Inlets/Catch Basins

All inlets, catch basins, and manhole castings must be pre-stamped with an appropriate “clean water” message. Manholes, catch basins and inlets shall be installed to provide human access to continuous underground storm sewers for the purpose of inspection and maintenance. The casting access minimum inside diameter shall be no less than 22 inches or a rectangular opening of no less than 22 inches by 22 inches. A sump with a minimum of 12 inches shall be provided
in all inlets and catch basins. Manholes shall be provided at the following locations:

1. Where two or more storm sewers converge.
2. Where pipe size or the pipe material changes.
3. Where a change in horizontal alignment occurs.
4. Where a change in pipe slope occurs.
5. At intervals in straight sections of sewer, not to exceed the maximum allowed. The maximum distance between storm sewer manholes shall be as shown in Table 4-2.

### TABLE 4-2

<table>
<thead>
<tr>
<th>Size of Pipe (Inches)</th>
<th>Maximum Distance (Feet)</th>
</tr>
</thead>
<tbody>
<tr>
<td>All Sizes</td>
<td>400</td>
</tr>
</tbody>
</table>

In addition to the above requirements, a minimum drop of 0.1 foot through manholes, inlets and catch basin structures must be provided. Pipe slope should not be so steep that inlets surcharge (i.e. hydraulic grade line should remain below rim elevation).

Catch basin and inlet inside sizing shall be as shown in Table 4-3 but not less than 1.5 times the diameter of the largest pipe entering the structure.

### TABLE 4-3

</tbody>
</table>

7. Manholes shall have a minimum of 48 inch inside diameter but not less than 1.5 times the largest diameter pipe entering the manhole.

8. Manholes, inlets, and catch basins shall also conform to the design and installation standards depicted in Figure 4-2 to 4-4.

### H. Inlet Sizing and Spacing

Inlets or drainage structures shall be utilized to collect surface water through grated openings and convey it to storm sewers, channels, or culverts. The inlet grate opening provided shall be adequate to pass the design 10-year flow with 50% of the sag inlet areas clogged. An overload channel from sag inlets to the overflow channel or basin shall be provided at sag inlets. Inlet design and spacing may be done using the hydraulic equations by manufacturers or orifice/weir equations. Use of the U.S. Army Corps of Engineers HEC-12 computer program is also an acceptable method. Gutter spread on continuous grades may be determined using the Manning's equation, or by using Figure 4-1. The maximum inlet spacing shall be 400 feet.

Further guidance regarding gutter spread calculation may be found in the latest edition of HERPICC Stormwater Drainage Manual, available from the Local Technical Assistance Program (LTAP). At the time of printing of this document, contact information for LTAP was:

Website: www.purdue.edu/INLTAP/

### I. Installation and Workmanship

Bedding and backfill materials around storm sewer pipes, sub-drains, and the associated structures shall not be less stringent than those set forth in the latest edition of the “INDOT Standard Specifications”. Additionally, ductile iron pipe
shall be laid in accordance with American Water Works Association (AWWA) C-600. Dips/sags on newly installed storm systems will not be allowed. Also, infiltration from cracks, missing pieces, and joints shall not be allowed. Variations from these standards must be justified and receive written acceptance from the City Engineer. All structures shall require inspection prior to backfill.

J. Materials

Storm sewer manholes, inlets, and catch basins shall be constructed of cast-in-place concrete or precast reinforced concrete. Material and construction shall conform to the latest edition of the Indiana Department of Transportation (INDOT) "Standard Specifications", Sections 702 and 720.

Pipe and fittings used in storm sewer construction shall be ductile iron pipe (AWWA C-151), polyvinyl chloride pipe (AASHTO M252), polyethylene pipe (AASHTO M252 or AASHTO M294), or concrete pipe (AASHTO M170). Other pipe and fittings not specified herein or in Sections 907-908 of the latest edition of the INDOT "Standard Specifications" may be used only when specifically authorized by the City Engineer. Pipe joints shall be flexible and watertight and shall conform to the requirements of Section 906, of the latest edition of the INDOT "Standard Specifications". If the storm sewer pipe is to be placed within a road right-of-way or in an area subject to loading, the pipe and fittings shall be Class III concrete. A higher class concrete may be required for cover depths in excess of 10 feet or less than 2 feet.

K. Special Hydraulic Structures

Special hydraulic structures required to control the flow of water in storm runoff drainage systems include junction chambers, drop manholes, stilling basins, and other special structures. The use of these structures shall be limited to those locations justified by prudent planning and by careful and thorough hydraulic engineering analysis. Certification of special structures by a certified Structural Engineer may also be required.

L. Connections to Storm Sewer System

To allow any connections to the storm sewer system, provisions for the connections shall be shown in the drainage calculations for the system. Specific language shall be provided in the protective covenants, on the record plat, or with the parcel deed of record, noting the ability or inability of the system to accommodate any permitted connections, for example, sump pumps and footing drains.
1. Sump pumps installed to receive and discharge groundwater or other stormwater shall be connected to the storm sewer where possible or discharged into a designated storm drainage channel/swale. Sump pumps installed to receive and discharge floor drain flow or other sanitary sewage shall be connected to the sanitary sewers. A sump pump shall be used for one function only, either the discharge of stormwater or the discharge of sanitary sewage.

2. Footing drains and perimeter drains may be connected to storm manholes, curb inlets, or catch basins in a manner approved by the City Engineer. If the preceding structures are not available for connection, then other connections may be made with the approval of and in a manner approved by the City Engineer.

3. Roof downspouts, roof drains, or roof drainage piping may be connected to storm manholes, curb inlets, or catch basins in a manner approved by the City Engineer. If the preceding structures are not available for connection, then other connections may be made with the approval of and in a manner approved by the City Engineer.

4. Garage and basement floor drains shall not be connected to the storm sewer system. These drains may be routed to a properly designed wet well.

5. Swimming pool drains shall not be connected to the storm sewers unless the water is properly dechlorinated, as defined in Appendix A, prior to connection and discharge to the storm sewer system.

In addition, none of the above mentioned devices shall be connected to any street underdrains, unless specifically authorized by the City Engineer.

M. Drainage System Overflow Design

Overflow path/ponding areas throughout the development resulting from a 100-year storm event, calculated based on all contributing drainage areas, on-site and off-site, in their proposed or reasonably anticipated land use and with storm pipe system assumed completely plugged, shall be determined, clearly shown as hatched area on the plans, and a minimum width of 30 feet along the centerline of the flow path contained in permanent drainage easements. A statement shall be added to the plat that refers the viewer to the construction plans to see the entire extent of overflow path as hatched areas. No fences or landscaping can be constructed within the easement areas that may impede the free flow of stormwater. These areas are to be maintained by the property owners or be designated as common areas that are to be maintained by the homeowners.
association. The Lowest Adjacent Grade for all residential, commercial, or industrial buildings shall be set a minimum of 1 foot above the noted overflow path/ponding elevation.

All buildings shall have a minimum flood protection grade shown on the secondary plat. Minimum Flood Protection Grade of all structures fronting a pond or open ditch shall be no less than 2 feet above any adjacent 100-year local or regional flood elevations, whichever is greater, for all windows, doors, unsealed pipe entrances, window well rim elevations, and any other structure member where floodwaters can enter a building.

The overflow path/ponding may be modeled as successive series of natural ponds and open channel segments. Ponds should be modeled similar to that discussed for modeling depressional areas in Chapter 6. Channels should be modeled according to modeling techniques discussed in Chapter 5. The calculations for determining the 100-year overflow path/ponding elevations may be based on hand calculation methods utilizing normal depth calculations and storage routing techniques or performed by computer models. Examples of computer models that either individually or in combination with other models can handle the required computations include TR-20, HEC-HMS, and HEC-1, combined with HEC-RAS. Other models may be acceptable. However, their use must be accepted by the City Engineer prior to their utilization.

Values in Table 4-4 may be utilized as an alternative to the above-noted detailed calculations for determining the required pad elevations of buildings near an overflow path.

**TABLE 4-4**

</tbody>
</table>

If Table 4-4 is used, the City Engineer reserves the right to require independent calculations to verify that the proposed building pads provide approximately 1 foot of freeboard above the anticipated overflow path/ponding elevations.

In the case of existing upstream detention, an allowance equivalent to the reduction in flow rate provided may be made for upstream detention only when: (1) such detention and release rate have previously been accepted by the City of Engineer or the City official charged with the approval authority at the time of the acceptance, and (2) evidence of its construction and maintenance can be shown.

STANDARD DETAIL
STORM SEWER CATCH BASIN
Dwn. By: D. Rodgers
REV. DATE: 01/30/07
CATCH BASIN CONSTRUCTION SPECIFICATIONS

1. The following materials are acceptable for catch basin construction:
   A. 8 inch wide hollow concrete blocks, grouted full.
   B. 8 inch wide solid concrete blocks.
   C. Precast or Cast-in-place concrete may be used with the following stipulations:
      a. concrete must be at least 6 inches thick
      b. top 6 inches (minimum) of structure must be constructed of solid concrete blocks.

2. Construct Poured Concrete Base as shown in the drawing.

3. Concrete Material shall meet the requirements of Section 702 of the Indiana Department of Transportation Standard Specifications.

5. The inside dimensions of the structure shall match the opening dimensions of the casting. The entire flange of the casting shall bear upon the top of the structure.

6. All voids around the pipe shall be filled with non-shrink grout and shall be smooth and flush with the inside wall surfaces. The construction shall be watertight.

7. All Inlet castings must be pre-stamped with an appropriate "clean water" message.

CITY OF GREENFIELD
STANDARD DETAIL
STORM SEWER MANHOLE
Dwn. By: D. Rodgers
REV. DATE: 01/30/07
STORM SEWER MANHOLE SPECIFICATIONS

I. MATERIALS

A. CASTING
1. Casting shall be East Jordan Iron Works casting #1020 & 1022 or approved equal.
2. Lid shall be stamped with the words “CITY OF GREENFIELD – STORM” and an appropriate “clean water” message.
3. A minimum of 4” and a maximum of 12” of concrete adjustment rings shall be installed under the casting.
4. Joint sealant under the casting, between the adjustment rings and between the adjustment rings and the manhole shall be two rings of non-hardening butyl rubber rope, Conscoal or equal. (Kent Seal is not acceptable)

B. CONCRETE MANHOLE
1. 48” diameter precast concrete sections shall be used to construct the manhole barrel.
2. A flat-top may not be used in place of a cone section unless specifically approved by City Officials before construction begins.
3. “O-ring” gaskets must be used in the joints between manhole sections.
4. The finished manhole must be watertight.
5. The steps shall be made of plastic-coated steel and shall be placed as shown on the drawing.

C. BEDDING AND BACKFILL
1. The manhole must be constructed directly upon undisturbed soil or a minimum of 6” of compacted crushed stone.
2. Granular material must be used to backfill the excavation. The material must be mechanically compacted in lifts not to exceed 12”.

II. EXECUTION

A. INSPECTIONS
1. The manhole must be inspected by the Wastewater Treatment and Collections Department designated inspector before the excavation is backfilled.
Call 462-8530
OPEN CHANNEL DESIGN STANDARDS AND SPECIFICATIONS

All channels, whether private or public, and whether constructed on private or public land, shall conform to the City of Greenfield Public Improvement Design Standards as well as other design requirements contained herein.

A. Design Storm Frequencies

1. All channels and swales shall accommodate, at a minimum, peak runoff from a 10-year return frequency storm calculated based on methodology described in Chapter 2. The storm duration shall be equal to the time of concentration for the drainage area if the Rational Method is utilized for analysis. In computer-based analysis, the duration is as noted in the applicable methodology associated with the computer program.

2. Channels with a carrying capacity of more than 30 cfs at bank-full stage shall be capable of accommodating peak runoff for a 50-year return frequency storm within the drainage easement.

3. Channel facilities functioning as a major drainage system, as defined in Appendix A, must also meet IDNR design standards in addition to the City of Greenfield standards. In case of discrepancy, the most restrictive requirements shall apply.

4. The 10-year storm design flow for residential rear and side lot swales shall not exceed 4 cfs. Unless designed as a Post-construction stormwater quality BMP, the maximum length of rear and side lot swales before reaching any inlet shall not exceed 300 feet and shall not convey flow from more than 3 lots.

5. Regardless of minimum design frequencies stated above, the performance of all parts of drainage system shall be checked for the 100-year flow conditions to insure that all buildings are properly located outside the 100-year flood boundary and that flow paths are confined to designated areas with sufficient easement.
B. Manning's Equation

The waterway area for channels shall be determined using Manning's Equation, where:

\[ A = \frac{Q}{V} \]

- **A** = Waterway area of channel in square feet
- **Q** = Discharge in cubic feet per second (cfs)
- **V** = Steady-State channel velocity, as defined by Manning’s Equation (See Chapter 4)

C. Backwater Method for Drainage System Analysis

The determination of 100-year water surface elevation along channels and swales shall be based on accepted methodology and computer programs designed for this purpose. Computer programs HEC-RAS, HEC-2, and ICPR are preferred programs for conducting such backwater analysis. The use of other computer models must be accepted in advance by the City Engineer.

D. Channel Cross-Section and Grade

1. The required channel cross-section and grade are determined by the design capacity, the material in which the channel is to be constructed, and the requirements for maintenance. A minimum depth may be required to provide adequate outlets for subsurface drains, tributary ditches, or streams. The channel grade shall be such that the velocity in the channel is high enough to prevent siltation but low enough to prevent erosion. Velocities less than 2 feet per second (fps) are not acceptable, as siltation will take place and ultimately reduce the channel cross-section area. The maximum permissible velocities in vegetated-lined channels are shown in Table 5-1. In addition to existing runoff, the channel design should incorporate increased runoff due to the proposed development.

2. Where depth of design flow is slightly below critical depth, channels shall have freeboard adequate to cope with the effect of hydraulic jumps.

3. Along the streets and roads, the bottom of the ditch should be low enough to install adequately-sized driveway culverts without creating "speed
bumps. The driveway culvert inverts shall be designed to adequately consider upstream and downstream culvert elevations.

4. Flow of a channel into a closed system is prohibited, unless runoff rate and head loss computations demonstrate the closed conduit to be capable of carrying the 100-year channel flow for developed conditions, either entirely or in combination with a defined overflow channel, with no reduction of velocity.

</tbody>
</table>

(1) From Soil Conservation Service, SCS-TP-61, "Handbook of Channel Design for Soil and Water Conservation".

(2) Use velocities exceeding 5 feet per second only where good channel ground covers and proper maintenance can be obtained.

(3) Do not use on slopes steeper than 10 percent except for vegetated side slopes in combination with a stone, concrete, or highly resistant vegetative center section.

(4) Do not use on slopes steeper than 5 percent except for vegetated side slopes in combination with a stone, concrete, or highly resistant vegetative center section.

(5) Annuals - use on mild slopes or as temporary protection until permanent covers are established.

(6) Use on slopes steeper than 5 percent is not recommended.
E. **Side Slopes**

1. Earthen channel and swale side slopes shall be no steeper than 3 horizontal to 1 vertical (3:1). Flatter slopes may be required to prevent erosion and for ease of maintenance.

2. Where channels will be lined with riprap, concrete, or other acceptable lining method, side slopes shall be no steeper than 2 horizontal to 1 vertical (2:1) with adequate provisions made for weep holes.

3. Side slopes steeper than 2 horizontal to 1 vertical (2:1) may be used for lined channels provided that the side lining is designed and constructed as a structural retaining wall with provisions for live and dead load surcharge.

4. When the design discharge produces a depth of greater than three (3) feet in the channel, appropriate safety precautions shall be added to the design criteria based on reasonably anticipated safety needs.

F. **Channel Stability**

1. Characteristics of a stable channel are:
   a. It neither promotes sedimentation nor degrades the channel bottom and sides.
   b. The channel banks do not erode to the extent that the channel cross-section is changed appreciably.
   c. Excessive sediment bars do not develop.
   d. Excessive erosion does not occur around culverts, bridges, outfalls or elsewhere.
   e. Gullies do not form or enlarge due to the entry of uncontrolled flow to the channel.

2. Channel stability shall be determined for an aged condition and the velocity shall be based on the design flow or the bankfull flow, whichever is greater, using an "n" value for various channel linings as shown in **Tables 4-1 and 5-1**. In no case is it necessary to check channel stability for discharges greater than that from a 100-year frequency storm.
3. Channel stability shall be checked for conditions representing the period immediately after construction. The velocity for this stability analysis shall be calculated for the expected flow from a 10-year frequency storm on the watershed, or the bankfull flow, whichever is smaller, and the "n" value for the newly constructed channels in fine-grained soils and sands may be determined in accordance with the "National Engineering Handbook 5, Supplement B, Soil Conservation Service" and shall not exceed 0.025. This reference may be obtained by contacting the National Technical Information Service in Springfield. The allowable velocity in the newly constructed channel may be increased by a maximum of 20 percent to reflect the effects of vegetation to be established under the following conditions:

a. The soil and site in which the channel is to be constructed are suitable for rapid establishment and support of erosion controlling vegetation.

b. Species of erosion controlling vegetation adapted to the area, and proven methods of establishment are shown.

c. The channel design includes detailed plans for establishment of vegetation on the channel side slopes.

G. Drainage of Swales

Minimum swale slopes are 1.0% unless designed to act as a Post-construction stormwater quality BMP. All flow shall be confined to the specific easements associated with each rear and side lot swale that are part of the minor drainage system. Unless designed to act as a stormwater quality BMP, vegetated swales shall have tile underdrains to dry the swales in accordance with the City of Greenfield Public Improvement Design Standards. Tile lines may be outletted through a drop structure at the ends of the swale or through a standard tile outlet. Further guidance regarding this subject may be found in the latest edition of the Indiana Drainage Handbook.

H. Appurtenant Structures

The design of channels will include provisions for operation and maintenance and the proper functioning of all channels, laterals, travelways, and structures associated with the project. Recessed inlets and structures needed for entry of surface and subsurface flow into channels without significant erosion or degradation shall be included in the design of channel improvements. The design will also provide for necessary floodgates, water level control devices, and any
other appurtenance structure affecting the functioning of the channels and the attainment of the purpose for which they are built.

The effects of channel improvements on existing culverts, bridges, buried cables, pipelines, and inlet structures for surface and subsurface drainage on the channel being improved and laterals thereto shall be evaluated to determine the need for modification or replacement. Culverts and bridges which are modified or added as part of channel improvement projects shall meet reasonable standards for the type of structure, and shall have a minimum capacity equal to the design discharge or governmental agency design requirements, whichever is greater.

I. Deposition of Spoil

Spoil material resulting from clearing, grubbing, and channel excavation shall be disposed of in a manner that will:

1. Minimize overbank wash.
2. Provide for the free flow of water between the channel and floodplain boundary unless the valley routing and water surface profiles are based on continuous dikes being installed.
3. Not hinder the development of travelways for maintenance.
4. Leave the right-of-way in the best condition feasible, consistent with the project purposes, for productive use by the owner.
5. Be accepted by the Indiana Department of Natural Resources or United States Army Corps of Engineers, if applicable.

J. Materials

Materials acceptable for use as channel lining are:

1. Grass (hand sown or hydroseed)
2. Revetment Riprap
3. Concrete
4. Hand Laid Riprap
5. Precast Cement Concrete Riprap
6. Gabions (or reno mattresses)
7. Straw or Coconut Mattings or erosion control blanket (only until grass is established)
Other lining materials must be accepted in writing by the City Engineer. Materials shall comply with the latest edition of the INDOT, "Standard Specifications".

K. Drainage System Overflow Design

Ponding and overflow path throughout the development resulting from a 100-year storm event, calculated based on all contributing drainage areas, on-site and off-site, in their proposed or reasonably anticipated land use and with the storm pipe system assumed completely plugged, shall be determined, clearly shown as hatched area on the plans, and a 30 feet along the centerline of the overflow path contained in permanent drainage easements. A statement shall be added to the plat that would refer the viewer to the construction plans to see the entire extent of overflow path as hatched areas. No fences or landscaping can be constructed within the easement areas that may impede the free flow of stormwater. These areas are to be maintained by the property owners or be designated as common areas that are to be maintained by the homeowners association. The Lowest Adjacent Grade for all residential, commercial, or industrial buildings shall be set a minimum of 1 foot above the noted overflow path/ponding elevation.

The overflow path/ponding may be modeled as successive series of natural ponds and open channel segments. Ponds should be modeled similar to that discussed for modeling depressional areas in Chapter 6. Channels should be modeled according to modeling techniques discussed earlier in this Chapter. The calculations for determining the 100-year overflow path/ponding elevations may be based on hand calculation methods utilizing normal depth calculations and storage routing techniques or performed by computer models. Examples of computer models that either individually or in combination with other models can handle the required computations include TR-20, HEC-HMS, and HEC-1, combined with HEC-RAS. Other models may be acceptable and must be accepted by the City Engineer prior to their utilization.

Values in Table 4-4 may be utilized as an alternative to the above-noted detailed calculations for determining the required pad elevations of buildings near an overflow path.

If Table 4-4 is used, the City Engineer reserves the right to require independent calculations to verify that the proposed building pads provide approximately 1 foot of freeboard above the anticipated overflow path/ponding elevations.

In the case of existing upstream detention, an allowance equivalent to the reduction in flow rate provided may be made for upstream detention only when: (1) such detention and release rate have previously been accepted by the City Engineer official charged with the approval authority at the time of the acceptance, and (2) evidence of its construction and maintenance can be shown.
Chapter Six

STORMWATER DETENTION DESIGN STANDARDS

The following shall govern the design of any improvement with respect to the detention of stormwater runoff. Basins shall be constructed to temporarily detain the stormwater runoff that exceeds the maximum peak release rate authorized by the Ordinance. The required volume of storage provided in these basins, together with such storage as may be authorized in other on-site facilities, shall be sufficient to control excess runoff from the 10-year or 100-year storm as explained below in Section “B.” Also, basins shall be constructed to provide adequate capacity to allow for sediment accumulation resulting from development and to permit the pond to function for reasonable periods between cleanings.

A. Acceptable Detention Facilities

The increased stormwater runoff resulting from a proposed development must be detained on-site by the provisions of appropriate wet bottom or dry bottom detention facilities, parking lots, or other acceptable techniques. Measures that retard the rate of overland flow and the velocity in runoff channels shall also be used to partially control runoff rates.

B. Allowable Release Rates

1. General Release Rates

Control devices shall limit the discharge to a rate such that the post-developed release rate from the site is no greater than 0.1 cfs per acre of development for 0-10 year return interval storms and 0.3 cfs per acre of developed area for 11 - 100 year return interval storms. The above fixed general release rates may be set at a lower value by the City Engineer for certain watersheds if more detailed data becomes available as a result of comprehensive watershed studies conducted and/or formally approved and adopted by the Board of Public Works and Safety. The applicant shall confirm the applicable release rates with the City Engineer prior to initiating the design calculations to determine whether a basin-specific rate has been established for the watershed.

The release rate, when computed for a pre-developed area that has more than one (1) outlet, must be based on the pre-developed discharge rate for each outlet point. The computed release rate for each outlet point shall not be exceeded at the respective outlet point even if the post-developed conditions would involve a different arrangement of outlet points.
2. **Site-Specific Release Rates for Sites with Depressional Storage**

The general release rates provided above may have to be further reduced when utilized for sites where depressional storage exists. If depressional storage exists at the site, site-specific release rates must be calculated according to methodology described in Chapter 2, accounting for the depressional storage by modeling it as a pond whose outlet is a weir at an elevation that stormwater can currently overflow the depressional storage area. Post developed release rate for sites with depressional storage shall be the 2-year pre-developed peak runoff rate for the post-developed 10-year storm and 10-year pre-developed peak runoff rate for the post-developed 100-year storm. In no case shall the calculated site-specific release rates be larger than general release rates provided above.

Depressional storage by definition does not have a direct gravity outlet but if in agricultural production, it is more than likely drained by a tile and should be modeled as “empty” at the beginning of a storm. The function of any existing depressional storage should be modeled using an event hydrograph model to determine the volume of storage that exists and its effect on the existing site release rate. To prepare such a model, certain information must be obtained, including delineating the tributary drainage area, the stage-storage relationship and discharge-rating curve, and identifying the capacity and elevation of the outlet(s).

The tributary area should be delineated on the best available topographic data. After determining the tributary area, a hydrologic analysis of the watershed should be performed, including, but not limited to, a calculation of the appropriate composite runoff curve number and time of concentration. Stage-storage data for the depressional area should be obtained from the site topography. The outlet must be clearly marked and any calculations performed to create a stage-discharge rating curve must be included with the stormwater submittal.

The depressional storage must be assumed to be filled, when determining the post-developed peak runoff rates, unless the City Engineer can be assured, through a dedicated easement, that the noted storage will be preserved in perpetuity.

3. **Management of Off-site Runoff**

Runoff from all upstream tributary areas (off-site land areas) may be bypassed around the detention/retention facility without attenuation. Such runoff may also be routed through the detention/retention facility, provided that a separate secondary outlet system is incorporated for the safe passage of such flows, i.e., not through the primary outlet of a detention facility. Unless the pond is being designed as a regional detention facility and therefore all off-site runoff to the pond detained, the primary outlet structure shall be sized and the invert elevation of the
secondary outlet for bypassing off-site runoff determined according to the on-site runoff only. To accomplish this, the 100-year on-site runoff must be determined by temporarily ignoring the off-site runoff and routed through the pond and through the primary outlet pipe. The resulting pond elevation would be the invert elevation of the secondary outlet. Once the size and location of primary outlet structure and the invert elevation of the secondary outlet for bypassing off-site runoff are determined by considering on-site runoff only, the size of the secondary outlet and the 100-year pond elevation is determined by routing the entire inflow, on-site and off-site, through the pond. Once the 100-year pond elevation is determined in this manner, the crest elevation of the open emergency weir is set at that elevation.

The efficiency of the detention/retention facility in controlling the on-site runoff may be severely affected if the off-site area is considerably larger than the on-site area. As a general guidance, on-line detention may not be effective in controlling on-site runoff where the ratio of off-site area to on-site area is larger than 5:1. Additional detention (above and beyond that required for on-site area) may be required by the City Engineer when the ratio of off-site area to on-site area is larger than 5:1.

4. **Downstream Restrictions**

   In the event the downstream receiving channel or storm sewer system is inadequate to accommodate the post-developed release rate provided above, then the allowable release rate shall be reduced to that rate permitted by the capacity of the receiving downstream channel or storm sewer system. Additional detention, as determined by the City Engineer, shall be required to store that portion of the runoff exceeding the capacity of the receiving sewers or waterways. When such downstream restrictions are suspected, the City Engineer may require additional analysis to determine the receiving system’s limiting downstream capacity.

   If the proposed development makes up only a portion of the undeveloped watershed upstream of the limiting restriction, the allowable release rate for the development shall be in direct proportion to the ratio of its drainage area to the drainage area of the entire watershed upstream of the restriction.

   As an alternative to reduction of release rates, the City Engineer may allow the applicant to pursue alleviating downstream restrictions. The applicant would be responsible for obtaining all permits and consents required and for incurring all expenses involved in such undertaking.

5. **Documentation of Results**
The results of the allowable release rate determinations as well as the modeling simulation results must be summarized in a table that shall be included in the Stormwater Drainage Technical Report and on the Drainage Plan. The table must include, for each eventual site outlet, the pre-developed acreage tributary to each eventual site outlet, the unit discharge allowable release rate used, the resulting allowable release rate in cfs for the post-developed 10-year and 100-year events, pre-developed 2-year flow rates in cfs as well as pre- and post-developed flow rates for 10- and 100-year events. The worksheet provided as Table 6-1 should be filled for each final site outlet.

C. General Detention Basin Design Requirements

1. The detention facility shall be designed in such a manner that a minimum of 90% of the maximum volume of water stored and subsequently released at the design release rate shall not result in a storage duration in excess of 48 hours from the start of the storm unless additional storms occur within the period. In other words, the design shall ensure that a minimum 90% of the original detention capacity is restored within 48 hours from the start of the design 100-year storm.

2. The 100-year elevation of stormwater detention facilities shall be separated by not less than 25 feet from any building or structure to be occupied. The Lowest Adjacent Grade (including walkout basement floor elevation) for all residential, commercial, or industrial buildings shall be set a minimum of 2 feet above the 100-year pond elevation or 2 feet above the emergency overflow weir elevation, whichever is higher. In addition to the Lowest Adjacent Grade requirements, any basement floor must be at least a foot above the normal water level of any wet-bottom pond or the local groundwater table, whichever is higher.

3. No detention facility or other water storage area, permanent or temporary, shall be constructed under or within twenty (20) feet of any pole or high voltage electric line. Likewise, poles or high voltage electric lines shall not be placed within twenty (20) feet of any detention facility or other water storage area.

4. All stormwater detention facilities shall be separated from any road right-of-way by no less than 50 feet, measured from the top of bank or the 100-year pool if no defined top of bank is present, using the most restrictive right-of-way possible. Use of guard rails, berms, or other structural measures may be considered in lieu of the above-noted setbacks.

5. Slopes no steeper than 3 horizontal to 1 vertical (3:1) for safety, erosion control, stability, and ease of maintenance shall be permitted.

6. Debris Guard designed in accordance to City of Greenfield Public Improvement Design Standards shall be provided for any pipe or opening.

7. Outlet control structures shall be designed to operate as simply as possible and shall require little or no maintenance and/or attention for proper operation. The outlet from the pond shall be a minimum of 0.5 foot above the normal water level of the receiving water body. They shall limit discharges into existing or planned downstream channels or conduits so as not to exceed the predetermined maximum authorized peak flow rate. If a control structure outlet from above ground facilities includes an orifice to
restrict the flow rate, such orifice shall be no less than 4 inches in diameter, even if the 4 inch diameter orifice results in a discharge that exceeds the predetermined maximum authorized peak flow release rates as determined using methodologies in Section B (above) and in Article 3, Section 3.2.A of the Ordinance.

8. Emergency overflow facilities such as a weir or spillway shall be provided for the release of exceptional storm runoff or in emergency conditions should the normal discharge devices become totally or partially inoperative. The overflow facility shall be of such design that its operation is automatic and does not require manual attention.

Emergency overflow facilities shall be designed to handle one and one-quarter (1.25) times the peak discharge and peak flow velocity resulting from the 100-year design storm event runoff from the entire contributing watershed draining to the detention/retention facility (pond total peak 100-year inflow), assuming post-development condition on-site and existing condition off-site.

The emergency overflow routing from the emergency overflow facility to an adequate receiving system must be positive (by gravity) and sized to handle the design flow of the emergency overflow facility as provided above. The noted emergency overflow path must be shown on the construction plans and on the plat, and a minimum width of 30 feet along the centerline of the flow path contained in permanent drainage easement. Such easement is necessary to ensure adequate maintenance access and no obstructions (including fences, landscape regarding, etc.) shall be allowed. The Lowest Adjacent Grade (including walkout basement floor elevation) for all residential, commercial, or industrial buildings shall be set a minimum of 2 feet above the elevation of the design flow along the path.

9. Grass or other suitable vegetative cover shall be provided along the banks of the detention storage basin. Vegetative cover around detention facilities must be maintained as appropriate. The City will not be responsible for maintenance of the detention pond and bank slopes.

10. Debris and trash removal and other necessary maintenance shall be performed on a regular basis to assure continued operation in conformance to design. The City will not be responsible for pond maintenance.

11. No residential lots, or any part thereof, shall be used for any part of a detention basin, assumed full to the 100-year water surface elevation or the emergency overflow weir elevation, whichever is higher. Detention basins, assumed full to the 100-year water surface elevation or the emergency overflow weir elevation, whichever is higher, shall be placed within a common area either platted or legally described and recorded as a
perpetual stormwater easement. A minimum of twenty-five (25) feet horizontally from the top of bank of the facility, or the 100-year pool if no defined top of bank is present, shall be dedicated as permanent stormwater easement if the above-noted boundary of the common area does not extend that far.

12. A minimum of a twenty (20) foot wide drainage and utility easement shall be provided for access to any detention basin.

D. Additional Requirements for Wet-Bottom Facility Design

Where part of a detention facility will contain a permanent pool of water, all the items required for detention storage shall apply. Also, a controlled positive outlet will be required to maintain the design water level in the wet bottom facility and provide required detention storage above the design water level. However, the following additional conditions shall apply:

1. Facilities designed with permanent pools or containing permanent lakes shall have a water area of at least one-half (0.5) acre with a minimum depth of eight (8) feet over the majority of pond area. If fish are to be used to keep the pond clean, a minimum depth of approximately ten (10) feet shall be maintained over at least 25 percent of the pond area. The remaining pond area shall have no extensive shallow areas, except as required to install the safety ramp, safety ledge, and BMPs. Construction trash or debris shall not be placed within the permanent pool. The pond design shall be according to the City of Greenfield Public Improvement Design Standards.

2. A safety ramp exit from the pond may be required in some cases and shall have a minimum width of twenty (20) feet and exit slope of 6 horizontal to 1 vertical (6:1). The safety ramp shall be constructed of suitable material to prevent structural instability due to vehicles or wave action.

3. Periodic maintenance is required in lakes to control weed and larval growth. The facility shall also be designed to provide for the easy removal of sediment that will accumulate during periods of reservoir operation. A means of maintaining the designed water level of the lake during prolonged periods of dry weather may also be required. The City will not be responsible for pond maintenance.

4. Methods to prevent pond stagnation, including but not limited to surface or sub-surface aeration or destratification facilities that can, at the minimum, achieve one complete pond volume turnover per day should be considered. Figure below shows a typical diffuser aeration system that
consists of a quiet air compressor at the shore, aeration tubing, and one or more sets of diffuser head(s).

![Diagram of aeration system]

Irregularly shaped ponds should be treated as two or three separate ponds. Likewise, larger ponds will also need multiple aeration units.

![Diagram of air compressor]

Design calculations to substantiate the effectiveness of proposed aeration facilities shall be submitted with final engineering plans. Agreements for the perpetual operation and maintenance of aeration facilities shall be prepared to the satisfaction of the City Engineer.

E. Additional Requirements for Dry-Bottom Facility Design

In addition to general design requirements, detention facilities that will not contain a permanent pool of water shall comply with the following requirements:

1. Provisions shall be incorporated into facilities for complete interior drainage of dry bottom facilities, including a minimum 1% bottom slope in all directions if tile underdrains are provided and a minimum of 2% if no underdrains are provided. A positive/gravity outlet is required for the underdrains in all dry-bottom detention facilities.

2. The maximum planned depth of stormwater stored shall not exceed four (4) feet when dry-bottom facilities are utilized in residential developments.

3. In excavated detention facilities, a minimum side slope of 3:1 shall be provided for stability.

F. Parking Lot Storage
Paved parking lots may be designed to provide temporary detention storage of stormwater on all or a portion of their surfaces. Outlets for parking lot storage of stormwater will be designed so as to empty the stored waters slowly. Depths of storage shall be limited to a maximum depth of seven (7) inches so as to prevent damage to parked vehicles and so that access to parked vehicles is not impaired. Ponding should in general, be confined to those positions of the parking lots farthest from the area served. A perpetual maintenance agreement must be executed by the owner or the developer and filed with the City of Greenfield before such detention method is allowed. In addition, the 100-year inundation boundary should be determined and clearly shown on the construction plans.

G. Detention Facilities in Floodplains

No detention facilities are allowed to be placed within floodplains of any regulated drain or watercourse that has more than one (1) square mile of contributing drainage area, whether designated as such on FEMA maps or not.

H. Joint Development of Control Systems

Stormwater control systems may be planned and constructed jointly by two or more developers as long as compliance with the Ordinance and Standards is maintained.

I. Diffused Outlets

When the allowable runoff is released in an area that is susceptible to flooding or erosion, the developer may be required to construct appropriate storm drains through such area to avert increased flood hazard caused by the concentration of allowable runoff at one point instead of the natural overland distribution. The requirement of diffused outlet drains shall be at the discretion of the City Engineer.

J. IDNR Requirements

All designs for basins to be constructed in the floodway of a stream with a drainage area of one square mile or more must also satisfy IDNR permit requirements.

K. Allowance for Sedimentation
Detention basins shall be designed with an additional ten (10) percent of available capacity to allow for sediment accumulation resulting from development and to permit the pond to function for reasonable periods between cleanings. Basins should be designed to collect sediment and debris in specific locations, such as a forebay, so that removal costs are kept to a minimum. The sediment allowance may be provided below the permanent pool elevation for wet-bottom ponds. No construction trash or debris shall be allowed to be placed within the permanent pool. If the pond is used as a sediment control measure during active construction, the performance sureties will not be released until sediment has been cleaned out of the pond and elevations and grades have been reestablished as noted in the accepted plans.
The requirements contained in this Chapter are intended to prevent stormwater pollution resulting from soil erosion and sedimentation or from mishandling of solid and hazardous waste. Practices and measures included herein should assure that no foreign substance, (e.g. sediment, construction debris, chemicals) be transported from a site and allowed to enter any drainageway, whether intentionally or accidentally, by machinery, wind, rain, runoff, or other means.

A. POLLUTANTS OF CONCERN DURING CONSTRUCTION

The major pollutant of concern during construction is sediment. Natural erosion processes are accelerated at a project site by the construction process for a number of reasons, including the loss of surface vegetation and compaction damage to the soil structure itself, resulting in reduced infiltration and increased surface runoff. Clearing and grading operations also expose subsoils which are often poorly suited to re-establish vegetation, leading to longer term erosion problems.

Problems associated with construction site erosion include: transport of pollutants attached to displaced sediment; increased turbidity (reduced light) in receiving waters; and recreational use impairment. The deposited sediment may pose direct toxicity to wildlife, or smother existing spawning areas and habitat. This siltation also reduces the flow capacity of waterways, resulting in increased flood hazards to the public.

Other pollutants of concern during the construction process are hazardous wastes or hydrocarbons associated with the construction equipment or processes. Examples include concrete washoff, paints, solvents, and hydrocarbons from refueling operations. Poor control and handling of toxic construction materials pose an acute (short-term) or chronic (long-term) risk of death to aquatic life, wildlife, and the general public.

B. EROSION AND SEDIMENT CONTROL REQUIREMENTS

The following principles should govern erosion and sediment control practices on all sites:

1. Sediment-laden water flowing from the site shall be detained by erosion control measures appropriate to minimize sedimentation.
2. Water shall not be discharged in a manner that causes erosion at or downstream of the point of discharge.

3. All access to building sites that cross a natural watercourse, drainage easement, or swale/channel shall have a culvert of appropriate size.

4. Wastes or unused building materials, including but not limited to garbage, debris, cleaning wastes, wastewater, toxic materials, and hazardous substances, shall not be carried by runoff from a site. All wastes shall be disposed of in a proper manner. No construction trash or debris shall be allowed to be placed within the permanent pool of the detention/retention ponds. If the pond is used as a sediment control measure during active construction, the performance sureties will not be released until sediment has been cleaned out of the pond and elevations and grades have been reestablished as noted in the accepted plans.

5. Sediment being tracked from a site onto public or private roadways shall be minimized. This can be accomplished initially by a temporary gravel construction entrance, in addition to a well-planned layout of roads, access drives, and parking areas.

6. Public or private roadways shall be kept cleared of accumulated sediment. Bulk clearing of sediment shall not include flushing the area with water.

7. All storm drain inlets shall be protected against sedimentation with barriers meeting accepted criteria, standards, and specifications, or shall be equipped with temporary catch basin inserts. Barriers installed to protect inlets shall be cleaned and maintained in a sufficient manner and frequency to provide adequate protection while allowing adequate drainage.

8. Runoff passing through a site from adjacent areas shall be controlled by diverting it around disturbed areas, where practical. Diverted runoff shall be conveyed in a manner that will not erode the channel and receiving areas. Alternatively, the existing channel may be left undisturbed or improved to prevent erosion or sedimentation from occurring.

9. Drainageways and swales shall be designed and adequately protected so that their final gradients and resultant velocities will not cause channel or outlet scouring.

10. All disturbed ground left inactive for fifteen (15) or more days shall be stabilized by seeding, sodding, mulching, covering, or by other equivalent erosion control measures.

11. Appropriate sediment control practices shall be installed prior to any land disturbance and thereafter whenever necessary.

12. During the period of construction activity at a site, erosion control measures
necessary to meet the requirements of the Ordinance shall be maintained by the applicant.

C. COMMON CONTROL PRACTICES

All erosion control and stormwater pollution prevention measures required to comply with the Ordinance shall meet the design criteria, standards, and specifications similar to or the same as those outlined in the “Indiana Drainage Handbook” and “Indiana Handbook for Erosion Control in Developing Areas”, both published by the Indiana Department of Natural Resources, or other comparable and reputable references. The City of Greenfield does reserve the right to deny the use of certain pollution prevention measures that may be outlined in the above references and may provide additional or alternative design criteria, standards, and specifications. **Table 7-1** lists some of the more common and effective practices for preventing stormwater pollution from construction sites. Details of each practice can be found in the Indiana Drainage Handbook, the Indiana Handbook for Erosion Control in Developing Areas, or in **Appendix C**. These practices should be used to protect *every* potential pollution pathway to stormwater conveyances.

Fact sheet Location: 1. Indiana Handbook for Erosion Control in Developing Areas, 1992 or later  
2. Indiana Drainage Handbook, 1999 or later
D. INDIVIDUAL LOT CONTROLS

Although individual lots within a larger development may not appear to contribute as much sediment as the overall development, the cumulative effect of lot development is of concern. From the time construction on an individual lot begins, until the individual lot is stabilized, the builder must take steps to:

1. protect adjacent properties from sedimentation;
2. prevent mud/sediment from depositing on the street;
3. protect drainage ways from erosion and sedimentation;
4. prevent sediment laden water from entering the storm sewer system;
5. prevent trash and other construction debris from leaving the building site or becoming a nuisance;
6. and, provide temporary or permanent seeding within fifteen (15) days of inactivity.

This can be accomplished using numerous erosion and sediment control measures. A standard erosion control plan for individual lots is provided in Appendix B. The standard plan includes perimeter silt fence, stabilized construction entrance, curb inlet protection, drop inlet protection, stockpile containment, stabilized drainage swales, downspout extensions, temporary seeding and mulching, and permanent vegetation. Every relevant measure shall be installed at each individual lot site.

Construction sequence on individual lots should be as follows:

1. Clearly delineate areas of trees, shrubs, and vegetation that are to be undisturbed. To prevent root damage, the areas delineated for tree protection should be at least the same diameter as the crown.
2. Install perimeter erosion control at construction limits where drainage is expected to leave the property.
3. Install erosion control to intercept runoff prior to entering drainage swales.
4. Avoid disturbing drainage swales if vegetation is established. If drainage swales are bare, install erosion control blankets or sod to immediately stabilize.
5. Install protection for all inlets and catch basins on the property.
6. Install curb inlet protection, on both sides of the road, for all inlets along the property frontage and along the frontage of adjacent lots, or install temporary catch basin inserts in each inlet and frequently clean.
7. Install a 2-3 inch stone or gravel construction entrance that extends from the street to the building pad.
8. Perform primary grading operations.
9. Contain erosion from any soil stockpiles created on-site with additional erosion control measures around the base.
10. Establish temporary seeding and mulch on disturbed areas.
11. Provide trash and construction debris storage and disposal.
12. Construct the home and install utilities.
13. Install downspout extenders once the roof and gutters have been constructed. Extenders should outlet to a stabilized area.
14. Seed any areas disturbed by construction and utilities installation with temporary seed mix within 3 days of completion of disturbance.
15. Grade the site to final elevations.
16. Install permanent seeding and mulch to stabilize site or install sod.

All erosion and sediment control measures must be properly maintained throughout construction. These control measures shall remain in place until temporary or permanent vegetation is established to a coverage of Seventy (70) percent over the entire disturbed area. Temporary and permanent seeding should be watered as needed until established. Additional information concerning individual lot erosion and sediment control may be found on the “Individual Lot Erosion and Sediment Control Plan and Certification” form in Appendix B of this manual or the IDNR, Division of Soil Conservation’s pamphlet titled “Erosion and Sediment Control for Individual Building Sites”.
A. INTRODUCTION

City of Greenfield has established a minimum standard that the measurement of the effectiveness of the control of stormwater runoff quality will be based on the management of Total Suspended Solids (TSS). This requirement is being adopted as the basis of the City of Greenfield stormwater quality management program for all areas of jurisdiction.

This section of the manual establishes minimum standards for the selection and design of construction water quality BMPs. The information provided in this Chapter establishes performance criteria for stormwater quality management and procedures to be followed when preparing a BMP plan for compliance. Post-Construction BMPs must be sized to treat the water quality volume, WQv, for detention-based BMPs or the water quality discharge, Qwq, for flow-through BMPs. Chapter 9 provides the methodology for calculating the WQv and Qwq values.

BMPs noted in this Chapter refer to post-construction BMPs, which continue to treat stormwater after construction has been completed and the site has been stabilized. Installing certain BMPs, such as bioretention areas and sand filters, prior to stabilization can cause failure of the measure due to clogging from sediment. If such BMPs are installed prior to site stabilization, they should be protected by traditional erosion control measures.

Conversely, detention ponds and other BMPs can be installed during construction and used as sediment control measures. In those instances, the construction sequence must require that the pond is cleaned out with pertinent elevations and storage and treatment capacities reestablished as noted in the accepted stormwater management plan.

B. INNOVATIVE BMPs

BMPs not previously accepted by the City Engineer must be certified by a professional engineer licensed in State of Indiana and accepted through the City Engineer. ASTM standard methods must be followed when verifying performance of new measures. New BMPs, individually or in combination, must meet the 80% TSS removal rate at 50-125 micron range (silt/fine sand) without re-entrainment and must have a low to medium maintenance requirement to be considered by the City Engineer. Testing to establish the TSS removal rate must be conducted by an independent testing facility, not the BMP manufacturer.
C. PRE-APPROVED BMPs

City of Greenfield has designated a number of pre-approved BMP methods to be used alone or in combination to achieve the 80% TSS removal stormwater quality goals for a given project. These BMP measures are listed along with their anticipated average TSS removal rates in Table 8-1. Pre-approved BMPs have been proven/are assumed to achieve the average TSS removal rates indicated in Table 8-1. Applicants desiring to use a different TSS removal rate for these BMPs must follow the requirements discussed above for Innovative BMPs. Details regarding the applicability and design of these pre-approved BMPs are contained within fact sheets presented in Appendix D.

Note that a single BMP measure may not be adequate to achieve the water quality goals for a project. It is for this reason that a “treatment train”, a number of BMPs in series, is often required for a project.

**Notes:**

A. Based on capture of 0.5-inch of runoff volume as best available data. Effectiveness directly related to captured runoff volume, increasing with larger capture volumes.

B. The removal rate for this category varies widely between various models and manufacturers. Independent testing must be provided, rather than the manufacturer’s testing data.

C. Must provide vendor data for removal rates.

D. Removal rates shown are based on typical results. These rates are also dependent on proper installation and maintenance. The ultimate responsibility for determining whether additional measures must be taken to meet the Ordinance requirements for site-specific conditions rests with the applicant.

METHODOLOGY FOR DETERMINATION OF REQUIRED SIZING OF BMPs

A. INTRODUCTION

Structural Water Quality BMPs are divided into two major classifications: detention BMPs and Flow-through BMPs. Detention BMPs impound (pond) the runoff to be treated, while flow through BMPs treat the runoff through some form of filtration process.

B. DETENTION BMP SIZING

Water Quality Detention BMPs must be designed to store the water quality volume for treatment. The water quality volume, WQv, is the storage needed to capture and treat the runoff from the first one inch of rainfall. The water quality volume is equivalent to one inch of rainfall multiplied by the volumetric runoff coefficient (Rv) multiplied by the site area, or:

\[ WQv = \frac{(P) (Rv) (A)}{12} \]

where:
- WQv = water quality volume (acre-feet)
- P = 1 inch of rainfall
- Rv = volumetric runoff coefficient
- A = area in acres

The volumetric runoff coefficient is a measure of imperviousness for the contributing area, and is calculated as:

\[ Rv = 0.05 + 0.009(I) \]

Where:
- I is the percent impervious cover

A proposed commercial site, for example, will be designed to drain to three different outlets, with the following drainage areas and impervious percentages:
Calculating the volumetric runoff coefficient for subareas A, B and C yields:

\[
\begin{align*}
R_v (\text{subarea A}) &= 0.05 + 0.009(80) = 0.77 \\
R_v (\text{subarea B}) &= 0.05 + 0.009(75) = 0.73 \\
R_v (\text{subarea C}) &= 0.05 + 0.009(77) = 0.74
\end{align*}
\]

The water quality volumes for these three areas are then calculated as:

\[
\begin{align*}
WQv (\text{subarea A}) &= (1")(R_v)(A)/12 = 0.77(7.5)/12 = 0.48 \text{ acre-feet} \\
WQv (\text{subarea B}) &= 0.73(4.3)/12 = 0.26 \text{ acre-feet} \\
WQv (\text{subarea C}) &= 0.74(6.0)/12 = 0.37 \text{ acre-feet}
\end{align*}
\]

Note that this example assumed no offsite sources of discharge through the water quality detention BMPs. If there were significant sources of off-site runoff (sometimes called runon for upstream areas draining to the site), the designer would have the option of diverting off-site runoff around the on-site systems, or the detention BMP must be sized to treat the water quality volume for the entire contributing area, including off-site sources.

C. FLOW THROUGH BMP SIZING

Flow-through BMPs are designed to treat runoff at a peak design flow rate through the system. Examples of flow through BMPs include catch basin inserts, sand filters, and grassed channels. Another flow through BMP which is gaining popularity is a dynamic separator. Dynamic separators are proprietary, and usually include an oil-water separation component.

The following procedure should be used to estimate peak discharges for flow through BMPs (adopted from Maryland, 2000). It relies on the volume of runoff computed using the Small Storm Hydrology Method (Pitt, 1994) and utilizes the NRCS, TR-55 Method.

Using the WQv methodology, a corresponding Curve Number (CNwq) is computed utilizing the following equation:

\[
CN_{wq} = \frac{1000}{\left[10 + 5P + 10Q_a - 10\sqrt{Q_a^2 + 1.25Q_aP}\right]}
\]
where:

\[ \text{CN}_{\text{wq}} = \text{curve number for water quality storm event} \]
\[ P = 1\" \text{ (rainfall for water quality storm event)} \]
\[ Q_a = \text{runoff volume, in inches} = 1\" \times R_v = R_v \text{ (inches)} \]
\[ R_v = \text{volumetric runoff coefficient (see previous section)} \]

Due to the complexity of the above equation, the water quality curve number is represented as a function of percent imperviousness in Figure 9-1.

The water quality curve number, \( \text{CN}_{\text{wq}} \), is then used in conjunction with the standard calculated time-of-concentration, \( t_c \), and drainage area as the basis input for TR-55 calculations. Using the SCS Type II distribution for 1 inch of rainfall in 24-hours, the water quality treatment rate, \( Q_{wq} \), can then be calculated.

</table>
DEFINITIONS

Acre-Foot (AF): A measure of water volume equal to the inundation of a flat one-acre area to a dept of one foot (43,560 cubic feet).

Administering authority: The designated unit of government given the authority to issue permits.

Agricultural land disturbing activity: Tillage, planting, cultivation, or harvesting operations for the production of agricultural or nursery vegetative crops. The term also includes pasture renovation and establishment, the construction of agricultural conservation practices, and the installation and maintenance of agricultural drainage tile. For purposes of this rule, the term does not include land disturbing activities for the construction of agricultural related facilities, such as barns, buildings to house livestock, roads associated with infrastructure, agricultural waste lagoons and facilities, lakes and ponds, wetlands; and other infrastructure.

Agricultural land use conservation practices: Use of land for the production of animal or plant life, including forestry, pasturing or yarding of livestock, and planting, growing, cultivating, and harvesting crops for human or livestock consumption. Practices that are constructed on agricultural land for the purposes of controlling soil erosion and sedimentation. These practices include grass waterways, sediment basins, terraces, and grade stabilization structures.

Amortization Period: The length of time used to repay a debt or mortgage or to depreciate an initial cost.

Antecedent Runoff Condition: The index of runoff potential before a storm event. The index, developed by the Soil Conservation Service (SCS), is an attempt to account for the variation of the SCS runoff curve number (CN) from storm to storm.

Backflow Preventer: Device that allows liquids to flow in only one direction in a pipe. Backflow preventers are used on sewer pipes to prevent a reverse flow during flooding situations.

Backwater: The rise in water surface elevation caused by some obstruction such as a narrow bridge opening, buildings or fill material that limits the area through which the water shall flow.

Base Flood Elevation: The water surface elevation corresponding to a flood having a one percent probability of being equaled or exceeded in a given year.

Base Flood: See "Regulatory Flood".

Base Flow: Stream discharge derived from groundwater sources as differentiated from surface runoff. Sometimes considered to include flows from regulated lakes or reservoirs.

Basement: A building story that is all or partly underground but having at least one-half of its height below the average level of the adjoining ground. A basement shall not
be counted as a story for the purpose of height regulations.

**Benchmark:** A marked point of known elevation from which other elevations may be established.

**Best Management Practices:** Design, construction, and maintenance practices and criteria for stormwater facilities that minimize the impact of stormwater runoff rates and volumes, prevent erosion, and capture pollutants.

**Bioretention** A vegetated depression located on the site that is designed to collect, store and infiltrate runoff. Typically includes a mix of amended soils and vegetation. Bioretention areas, or rain gardens, are landscaping features adapted to provide on-site treatment of stormwater runoff. They are commonly located in parking lot islands or within small pockets of residential land uses.

**Buffer Strip:** An existing, variable width strip of vegetated land intended to protect water quality and habitat.

**Building:** See “structure”.

**Capacity of a Storm Drainage Facility:** The maximum flow that can be conveyed or stored by a storm drainage facility without causing damage to public or private property.

**Catch Basin:** A chamber usually built at the curb line of a street for the admission of surface water to a storm drain or subdrain, having at its base a sediment sump designed to retain grit and detritus below the point of overflow.

**Centerline of Channel:** The deepest point of a channel.

**Channel Improvement:** Alteration, maintenance, or reconstruction of the channel area for the purpose of improving the channel capacity or overall drainage efficiency. The noted "improvement" does not necessarily imply water quality or habitat improvement within the channel or its adjacent area.

**Channel Modification:** Alteration of a channel by changing the physical dimensions or materials of its bed or banks. Channel modification includes damming, rip-rapping or other armoring, widening, deepening, straightening, relocating, lining, and significant removal of bottom or woody vegetation. Channel modification does not include the clearing of dead or dying vegetation, debris, or trash from the channel. Channelization is a severe form of channel modification typically involving relocation of the existing channel (e.g., straightening).

**Channel Stabilization:** Protecting the sides and bed of a channel from erosion by controlling flow velocities and flow directions using jetties, drops, or other structures and/or by lining the channel with vegetation, riprap, concrete, or other suitable lining material.

**Channel:** A portion of a natural or artificial watercourse which periodically or continuously contains moving water, or which forms a connecting link between two bodies of water. It has a defined bed and banks which serve to confine the water.

**Class V injection well:** A type of well, which typically has a depth greater than its largest surface dimension, emplaces fluids into the subsurface, and does not meet the definitions of Class I through Class IV wells as defined under 40 CFR 146.5. While the term includes the specific examples described in 40 CFR 144.81, septic systems that
serve more than one (1) single-family dwelling or provide service for non-
domestic waste, dug wells, bored wells, improved sinkholes, french drains,
infiltration sumps, and infiltration galleries, it does not include surface
impoundments, trenches, or ditches that are wider than they are deep.

Closed Conduit: A pipe, tube, or tile used for transmitting water.

Combined Sewer Overflow: A system designed and used to receive and transport combined sewage so that
during dry periods the wastewater is carried to a treatment facility. During storm
events, the excess water is discharged directly into a river, stream, or lake
without treatment.

Compensatory Storage: An artificial volume of storage within a floodplain used to balance the loss of
natural flood storage capacity when artificial fill or substructures are placed
within the floodplain.

Compost: Organic residue (or a mixture of organic residue and soil) that has undergone biological decomposition until it has become relatively stable humus.

Comprehensive Stormwater Management Program: A comprehensive stormwater program for effective management of stormwater quantity and quality throughout the community.

Constructed Wetland: A manmade shallow pool that creates growing conditions suitable for wetland
vegetation and is designed to maximize pollutant removal.

Construction activity: Land disturbing activities associated with the construction of infrastructure and structures. This term does not include routine ditch or road maintenance or minor landscaping projects.

Construction plan: A representation of a project site and all activities associated with the project.
The plan includes the location of the project site, buildings and other infrastructure, grading activities, schedules for implementation and other pertinent information related to the project site. A storm water pollution prevention plan is a part of the construction plan.

Construction site access: A stabilized stone surface at all points of ingress or egress to a project site, for the purpose of capturing and detaining sediment carried by tires of vehicles or other equipment entering or exiting the project site.

Contiguous: Adjoining or in actual contact with.

Contour Line: Line on a map which represents a contour or points of equal elevation.

Contour: An imaginary line on the surface of the earth connecting points of the same elevation.

Contractor or subcontractor: An individual or company hired by the project site or individual lot owner, their agent, or the individual lot operator to perform services on the project site.

Control Structure: A structure designed to control the rate of flow that passes through the structure,
given a specific upstream and downstream water surface elevation.

Conveyance: Any structural method for transferring stormwater between at least two points. The term includes piping, ditches, swales, curbs, gutters, catch basins, channels,
storm drains, and roadways.

**Convolution:** The process of translating precipitation excess into a runoff hydrograph.

**Crawl Space:** Low space below first floor of a house where there has not been excavation deep enough for a basement, usually less than seven (7) feet in depth, but where there is access for pipes, ducts, utilities and similar equipment.

**Critical Duration Analysis:** The process of testing different rainfall durations to find that “critical duration”, which produces the highest peak runoff or the highest storage volume.

**Cross-Section:** A graph or plot of ground elevation across a stream valley or a portion of it, usually along a line perpendicular to the stream or direction of flow.

**Crown of Pipe:** The elevation of top of pipe.

**Cubic Feet Per Second (CFS):** Used to describe the amount of flow passing a given point in a stream channel. One cubic foot per second is equivalent to approximately 7.5 gallons per second.

**Culvert:** A closed conduit used for the conveyance of surface drainage water under a roadway, railroad, canal or other impediment.

**Curve Number (CN):** The Soil Conservation Service index that represents the combined hydrologic effect of soil, land use, land cover, hydrologic condition and antecedent runoff condition.

**Dam:** A barrier to confine or impound water for storage or diversion, to prevent gully erosion, or to retain soil, sediment, or other debris.

**Damage:** Measurable rise in flood heights on buildings currently subject to flooding, flooding of buildings currently not subject to flooding and increases in volume or velocity to the point where the rate of land lost to erosion and scour is substantially increased.

**Datum:** Any level surface to which elevations are referred, usually Mean Sea Level.

**Dechlorinated swimming pool discharge:** Chlorinated water that has either sat idle for seven (7) days following chlorination prior to discharge to the MS4 conveyance, or, by analysis, does not contain detectable concentrations (less than five-hundredths (0.05) milligram per liter) of chlorinated residual.

**Depressional Storage Areas:** Non-riverine depressions in the earth where stormwater collects. The volumes are often referred to in units of acre-feet.

**Design Storm:** A selected storm event, described in terms of the probability of occurring once within a given number of years, for which drainage or flood control improvements are designed and built.

**Detention Basin:** A facility constructed or modified to restrict the flow of storm water to a prescribed maximum rate, and to detain concurrently the excess waters that accumulate behind the outlet.

**Detention Facility:** A facility designed to detain a specified amount of stormwater runoff assuming a specified release rate. The volumes are often referred to in units of acre-feet.

**Detention Storage:** The temporary detaining of stormwater in storage facilities, on rooftops, in
streets, parking lots, school yards, parks, open spaces or other areas under predetermined and controlled conditions, with the rate of release regulated by appropriately installed devices.

**Detention Time:** The theoretical time required to displace the contents of a tank or unit at a given rate of discharge (volume divided by rate of discharge).

**Detention:** Managing stormwater runoff by temporary holding and controlled release.

**Detritus:** Dead or decaying organic matter; generally contributed to stormwater as fallen leaves and sticks or as dead aquatic organisms.

**Developer:** Any person financially responsible for construction activity, or an owner of property who sells or leases, or offers for sale or lease, any lots in a subdivision.

**Development:** Any man-made change to improved or unimproved real estate including but not limited to:

1. Construction, reconstruction, or placement of a building or any addition to a building;
2. Construction of flood control structures such as levees, dikes, dams or channel improvements;
3. Construction or reconstruction of bridges or culverts;
4. Installing a manufactured home on a site, preparing a site for a manufactured home, or installing a recreational vehicle on a site for more than hundred eight (180) days;
5. Installing utilities, erection of walls, construction of roads, or similar projects;
6. Mining, dredging, filling, grading, excavation, or drilling operations;
7. Storage of materials; or
8. Any other activity that might change the direction, height, or velocity of flood or surface waters.

“Development” does not include activities such as the maintenance of existing buildings and facilities such as painting, re-roofing, resurfacing roads, or gardening, plowing and similar agricultural practices that do not involve filling, grading, excavation, or the construction of permanent buildings.

**Direct Release:** A method of stormwater management where runoff from a part or the entire development is released directly to the receiving stream without providing detention.

**Discharge:** Usually the rate of water flow. A volume of fluid passing a point per unit time commonly expressed as cubic feet per second, cubic meters per second, gallons per minute, or millions of gallons per day.

**Disposal:** The discharge, deposit, injection, spilling, leaking, or placing of any solid waste or hazardous waste into or on any land or water so that the solid waste or hazardous waste, or any constituent of the waste, may enter the environment, be
emitted into the air, or be discharged into any waters, including.

**Ditch:** A man-made, open drainageway in or into which excess surface water or groundwater drained from land, stormwater runoff, or floodwaters flow either continuously or intermittently.

**Drain:** A buried slotted or perforated pipe or other conduit (subsurface drain) or a ditch (open drain) for carrying off surplus groundwater or surface water.

**Drainage Area:** The area draining into a stream at a given point. It may be of different sizes for surface runoff, subsurface flow and base flow, but generally the surface runoff area is considered as the drainage area.

**Drainage Classification (soil):** As a natural condition of the soil, drainage refers to both the frequency and duration of periods when the soil is free of saturation. Soil drainage conditions are defined as:

- **Well-drained**—Excess water drains away rapidly, and no mottling occurs within 36 in. of the surface.

- **Moderately well drained**—Water is removed from the soil somewhat slowly resulting in small but significant periods of wetness, and mottling occurs between 18 and 36 in.

- **Somewhat poorly drained**—Water is removed from the soil slowly enough to keep it wet for significant periods but not all of the time, and mottling occurs between 8 to 18 in.

- **Poorly drained**—Water is removed so slowly that it is wet for a large part of the time, and mottling occurs between 0 and 8 in.

- **Very poorly drained**—Water is removed so slowly that the water table remains at or near the surface for the greater part of the time; there may also be periods of surface ponding; the soil has a black to gray surface layer with mottles up to the surface.

**Drainage:** The removal of excess surface water or groundwater from land by means of ditches or subsurface drains. Also see Natural drainage.

**Drop Manhole:** Manhole having a vertical drop pipe connecting the inlet pipe to the outlet pipe. The vertical drop pipe shall be located immediately outside the manhole.

**Dry Well:** A type of infiltration practice that allows stormwater runoff to flow directly into the ground via a bored or otherwise excavated opening in the ground surface.

**Dry-Bottom Detention Basin:** A basin designed to be completely dewatered after having provided its planned detention of runoff during a storm event.

**Duration:** The time period of a rainfall event.

**Earth Embankment:** A man-made deposit of soil, rock, or other material often used to form an impoundment.

**Elevation Certificate:** A form published by the Federal Emergency Management Agency that is used to

Emergency Spillway: Usually a vegetated earth channel used to safely convey flood discharges around an impoundment structure.

Energy Dissipater: A device to reduce the energy of flowing water.

Environment: The sum total of all the external conditions that may act upon a living organism or community to influence its development or existence.

Erosion and sediment control measure: A practice, or a combination of practices, to control erosion and resulting sedimentation and/or off-site damages.

Erosion and sediment control system: The use of appropriate erosion and sediment control measures to minimize sedimentation by first reducing or eliminating erosion at the source and then as necessary, trapping sediment to prevent it from being discharged from or within a project site.

Erosion control plan: A written description and site plan of pertinent information concerning erosion control measures designed to meet the requirements of the Ordinance.

Erosion: The wearing away of the land surface by water, wind, ice, gravity, or other geological agents. The following terms are used to describe different types of water erosion:

- **Accelerated erosion**—Erosion much more rapid than normal or geologic erosion, primarily as a result of the activities of man.

- **Channel erosion**—An erosion process whereby the volume and velocity of flow wears away the bed and/or banks of a well-defined channel.

- **Gully erosion**—An erosion process whereby runoff water accumulates in narrow channels and, over relatively short periods, removes the soil to considerable depths, ranging from 1-2 ft. to as much as 75-100 ft.

- **Rill erosion**—An erosion process in which numerous small channels only several inches deep are formed; occurs mainly on recently disturbed and exposed soils (see Rill).

- **Splash erosion**—The spattering of small soil particles caused by the impact of raindrops on wet soils; the loosened and spattered particles may or may not be subsequently removed by surface runoff.

- **Sheet erosion**—The gradual removal of a fairly uniform layer of soil from the land surface by runoff water.

Extended Dry Detention: A dry detention basin that has been designed to increase the length of time that storm water will be detained, typically between 24-40 hours, to allow sediment particles and associated pollutants to settle out.
Extraterritorial Jurisdiction (ETJ): Areas located outside the corporate limits of a community over which the community has statutory development authority.

Farm or Field Tile: A pipe installed in an agricultural area to allow subsurface drainage of farmland for the purpose of agricultural production.

Filter Strip: Usually a long, relatively narrow area (usually, 20-75 feet wide) of undisturbed or planted vegetation used near disturbed or impervious surfaces to filter stormwater pollutants for the protection of watercourses, reservoirs, or adjacent properties.

Final stabilization: The establishment of permanent vegetative cover or the application of a permanent nonerosive material to areas where all land disturbing activities have been completed and no additional land disturbing activities are planned under the current permit.

Floatable: Any solid waste that will float on the surface of the water.

Flood (or Flood Waters): A general and temporary condition of partial or complete inundation of normally dry land areas from the overflow, the unusual and rapid accumulation, or the runoff of surface waters from any source.

Flood Boundary and Floodway Map (FBFM): A map prepared by the Federal Emergency Management Agency depicting the FEMA designated floodways within a community. This map also includes delineation of the 100-year and 500-year floodplain boundaries and the location of the Flood Insurance Study cross-sections.

Flood Crest: The maximum stage or elevation reached or expected to be reached by the waters of a specific flood at a given time.

Flood Duration: The length of time a stream is above flood stage or overflowing its banks.

Flood Easement: Easement granted to identify areas inundated by the 100-year flood and prohibit or severely restrict development activities.

Flood Elevation: The elevation at all locations delineating the maximum level of high waters for a flood of given return period.

Flood Fighting: Actions taken immediately before or during a flood to protect human life and to reduce flood damages such as evacuation, emergency sandbagging and diking.

Flood Forecasting: The process of predicting the occurrence, magnitude and duration of an imminent flood through meteorological and hydrological observations and analysis.

Flood Frequency: A statistical expression of the average time period between floods equaling or exceeding a given magnitude. A 100-year flood, for example, has a magnitude expected to be equaled or exceeded on the average of once every hundred years; such a flood has a one-percent chance of being equaled or exceeded in any given year. Often used interchangeably with "recurrence interval".

Flood Hazard Area: Any floodplain, floodway, floodway fringe, or any combination thereof which is subject to inundation by the regulatory flood; or any flood plain as delineated by Zone A on a Flood Hazard Boundary Map.
**Flood Hazard Boundary Map (FHBM):** A map prepared by the Federal Emergency Management Agency that depicts Special Flood Hazard Areas as a Zone A within a community. There are no study text, base flood elevations, or floodways associated with this map.

**Flood Insurance Rate Map (FIRM):** A map prepared by the Federal Emergency Management Agency that depicts Special Flood Hazard Areas within a community. This map also includes the 100-year or Base Flood Elevation at various locations along the watercourses. More recent versions of the FIMR may also show the FEMA designated floodway boundaries and the location of the Flood Insurance Study cross-sections.

**Flood Insurance Study (FIS):** A study prepared by the Federal Emergency Management agency to assist a community participating in the National Flood Insurance Program in its application of the program regulations. The study consists of a text which contains community background information with respect to flooding, a floodway data table, summary of flood discharges, flood profiles, a Flood Insurance Rate Map, and a Flood Boundary and Floodway Map.

**Flood Profile:** A graph showing the relationship of water surface elevation to a specific location, the latter generally expressed as distance above the mouth of a stream of water flowing in a channel. It is generally drawn to show surface elevation for the crest or a specific magnitude of flooding, but may be prepared for conditions at any given time or stage.

**Flood Protection Grade (FPG):** The elevation of the regulatory or 100-year flood plus two (2) feet at any given location in the Special Flood Hazard Area or 100-year floodplain.

**Flood Protection Grade:** The elevation of the lowest floor of a building, including the basement, which shall be two feet above the elevation of the regulatory flood.

**Flood Resistant Construction (Flood Proofing):** Additions, changes or adjustments to structures or property that are designed to reduce or eliminate the potential for flood damage.

**Flood Storage Areas:** Depressions, basins, or other areas that normally stand empty or partially empty, but fill with rainfall runoff during storms to hold the runoff and reduce downstream flow rates. The volumes are often referred to in units or acre-feet.

**Floodplain Management:** The operation of a program of corrective and preventive measures for reducing flood damage, including but not limited to flood control projects, floodplain land use regulations, flood proofing of buildings, and emergency preparedness plans.

**Floodplain Regulations:** General term applied to the full range of codes, ordinances and other regulations relating to the use of land and construction within floodplain limits. The term encompasses zoning ordinances, subdivision regulations, building and housing codes, encroachment laws and open area (space) regulations.

**Floodplain:** The channel proper and the areas adjoining the channel which have been or hereafter may be covered by the regulatory or 100-year flood. Any normally dry land area that is susceptible to being inundated by water from any natural source. The floodplain includes both the floodway and the floodway fringe districts.

**Floodway Fringe:** That portion of the flood plain lying outside the floodway, which is inundated by the regulatory flood.
**Floodway:**
The channel of a river or stream and those portions of the floodplains adjoining the channel which are reasonably required to efficiently carry and discharge the peak flow of the regulatory flood of any river or stream.

**Footing Drain:**
A drain pipe installed around the exterior of a basement wall foundation to relieve water pressure caused by high groundwater elevation.

**Forebay:**
A small pond placed in front of a larger retention/detention structure such as a wet pond, dry pond, or wetland to intercept and concentrate a majority of sediment that is coming into the system before it reaches the larger structure.

**Freeboard:**
An increment of height added to the base flood elevation to provide a factor of safety for uncertainties in calculations, unknown local conditions, wave actions and unpredictable effects such as those caused by ice or debris jams. (See Flood Protection Grade).

**French Drain:**
A drainage trench backfilled with a coarse, water-transmitting material; may contain a perforated pipe.

**Gabion:**
An erosion control structure consisting of a wire cage or cages filled with rocks.

**Gaging Station:**
A selected section of a stream channel equipped with a gage, stage recorder, or other facilities for determining stream stage and discharge.

**Garbage:**
All putrescible animal solid, vegetable solid, and semisolid wastes resulting from the processing, handling, preparation, cooking, serving, or consumption of food or food materials.

**Geographical Information System:**
A computer system capable of assembling, storing, manipulation, and displaying geographically referenced information. This technology can be used for resource management and development planning.

**Geotextile Fabric:**
A woven or non-woven, water-permeable synthetic material used to trap sediment particles, prevent the clogging of aggregates with fine grained soil particles, or as a separator under road aggregate.

**Geotextile Liner:**
A synthetic, impermeable fabric used to seal impoundments against leaks.

**Global Positioning System:**
A system that provides specially coded satellite signals that is processed by a receiver, which determines position, velocity, and time. The system is funded and controlled by the U.S. Department of Defense.

**Grade:**
(1) The inclination or slope of a channel, canal, conduit, etc., or natural ground surface usually expressed in terms of the percentage the vertical rise (or fall) bears to the corresponding horizontal distance. (2) The finished surface of a canal bed, roadbed, top of embankment, or bottom of excavation; any surface prepared to a design elevation for the support of construction, such as paving or the laying of a conduit. (3) To finish the surface of a canal bed, roadbed, top of embankment, or bottom of excavation, or other land area to a smooth, even condition.

**Grading:**
The cutting and filling of the land surface to a desired slope or elevation.

**Grass:**
A member of the botanical family Gramineae, characterized by blade-like leaves that originate as a sheath wrapped around the stem.
<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Grassed Waterway</td>
<td>A natural or constructed waterway, usually broad and shallow, covered with erosion-resistant grasses and used to conduct surface water from an area.</td>
</tr>
<tr>
<td>Ground Cover (horticulture)</td>
<td>Low-growing, spreading plants useful for low-maintenance landscape areas.</td>
</tr>
<tr>
<td>Groundwater Recharge</td>
<td>The infiltration of water into the earth. It may increase the total amount of water stored underground or only replenish supplies depleted through pumping or natural discharge.</td>
</tr>
<tr>
<td>Groundwater</td>
<td>Accumulation of underground water - natural or artificial. The term does not include man-made underground storage or conveyance structures.</td>
</tr>
<tr>
<td>Habitat</td>
<td>The environment in which the life needs of a plant or animal are supplied.</td>
</tr>
<tr>
<td>Hard Surface</td>
<td>See “Impervious Surface.</td>
</tr>
<tr>
<td>High Water</td>
<td>Maximum designed permitted, or regulated water level for an impoundment.</td>
</tr>
<tr>
<td>Household Hazardous Waste</td>
<td>Solid waste generated by households that is ignitable, toxic, reactive, corrosive, or otherwise poses a threat to human health or the environment.</td>
</tr>
<tr>
<td>Hydraulic Grade Line (HGL)</td>
<td>The HGL is equal to the water surface for channel flow whereas for pressure flow it is the piezometric surface.</td>
</tr>
<tr>
<td>Hydraulics</td>
<td>A branch of science that deals with the practical application of the mechanics of water movement. A typical hydraulic study is undertaken to calculate water surface elevations.</td>
</tr>
<tr>
<td>Hydrodynamic Loads</td>
<td>Forces imposed on structures by floodwaters due to the impact of moving water on the upstream side of the structure, drag along its sides, and eddies or negative pressures on its downstream side.</td>
</tr>
<tr>
<td>Hydrograph</td>
<td>A graph showing either the discharge, stage (depth), velocity, or volume of water with respect to time for a given point on a stream drainage basin, or a lake</td>
</tr>
<tr>
<td>Hydrologic Unit Code</td>
<td>A numeric United States Geologic Survey code that corresponds to a watershed area. Each area also has a text description associated with the numeric code.</td>
</tr>
<tr>
<td>Hydrology</td>
<td>The science of the behavior of water in the atmosphere, on the surface of the earth, and underground. A typical hydrologic study is undertaken to compute flow rates associated with specified flood events.</td>
</tr>
<tr>
<td>Hydrometeorologic</td>
<td>Water-related meteorological data such as rainfall or runoff.</td>
</tr>
<tr>
<td>Hydrostatic Loads</td>
<td>Those loads or pressures resulting from the static mass of water at any point of floodwater contact with a structure. They are equal in all direction and always act perpendicular to the surface on which they are applied. Hydrostatic loads can act vertically on structural members such as floors, decks and roofs, and can act laterally on upright structural members such as walls, piers, and foundations.</td>
</tr>
<tr>
<td>IDNR</td>
<td>Indiana Department of Natural Resources.</td>
</tr>
<tr>
<td>Illicit Discharge</td>
<td>Any discharge to a conveyance that is not composed entirely of stormwater except naturally occurring floatables, such as leaves or tree limbs.</td>
</tr>
<tr>
<td><strong>Impact Areas:</strong></td>
<td>Areas defined or mapped that are unlikely to be easily drained because of one or more factors including but not limited to any of the following: soil type, topography, land where there is not adequate outlet, a floodway or floodplain, land within 75 feet of each bank of any regulated drain or within 75 feet from the centerline of any regulated tile ditch.</td>
</tr>
<tr>
<td><strong>Impaired Waters:</strong></td>
<td>Waters that do not or are not expected to meet applicable water quality standards, as included on IDEM’s CWA Section 303(d) List of Impaired Waters.</td>
</tr>
<tr>
<td><strong>Impervious surface:</strong></td>
<td>Surfaces, such as pavement and rooftops, which prevent the infiltration of stormwater into the soil.</td>
</tr>
<tr>
<td><strong>Individual building lot:</strong></td>
<td>A single parcel of land within a multi-parcel development.</td>
</tr>
<tr>
<td><strong>Individual lot operator:</strong></td>
<td>A contractor or subcontractor working on an individual lot.</td>
</tr>
<tr>
<td><strong>Individual lot owner:</strong></td>
<td>A person who has financial control of construction activities for an individual lot.</td>
</tr>
<tr>
<td><strong>INDOT:</strong></td>
<td>Indiana Department of Transportation. Generally used here to refer to specifications contained in the publication &quot;INDOT Standard Specifications.&quot;</td>
</tr>
<tr>
<td><strong>Infiltration practices:</strong></td>
<td>Any structural BMP designed to facilitate the percolation of run-off through the soil to ground water. Examples include infiltration basins or trenches, dry wells, and porous pavement.</td>
</tr>
<tr>
<td><strong>Infiltration:</strong></td>
<td>Passage or movement of water into the soil.</td>
</tr>
<tr>
<td><strong>Infiltration Swales:</strong></td>
<td>A depressed earthen area that is designed to promote infiltration.</td>
</tr>
<tr>
<td><strong>Infiltration Basin</strong></td>
<td>A shallow impoundment which is designed to infiltrate stormwater into the soil.</td>
</tr>
<tr>
<td><strong>Inlet:</strong></td>
<td>An opening into a storm drain system for the entrance of surface storm water runoff, more completely described as a storm drain inlet.</td>
</tr>
<tr>
<td><strong>Intermittent Stream:</strong></td>
<td>A stream that conveys water only during wet periods, especially after storm events.</td>
</tr>
<tr>
<td><strong>Invert:</strong></td>
<td>The inside bottom of a culvert or other conduit.</td>
</tr>
<tr>
<td><strong>Junction Chamber:</strong></td>
<td>A converging section of conduit, usually large enough for a person to enter, used to facilitate the flow from one or more conduits into a main conduit.</td>
</tr>
<tr>
<td><strong>Land Surveyor:</strong></td>
<td>A person licensed under the laws of the State of Indiana to practice land surveying.</td>
</tr>
<tr>
<td><strong>Land-disturbing Activity:</strong></td>
<td>Any man-made change of the land surface, including removing vegetative cover that exposes the underlying soil, excavating, filling, transporting and grading.</td>
</tr>
</tbody>
</table>
| **Larger common plan of development or sale:** | A plan, undertaken by a single project site owner or a group of project site owners acting in concert, to offer lots for sale or lease; where such land is contiguous, or is known, designated, purchased or advertised as a common unit or by a common name, such land shall be presumed as being offered for sale or lease as part of a larger common plan. The term also includes phased or other
construction activity by a single entity for its own use.

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lateral Storm Sewer:</td>
<td>A drain that has inlets connected to it but has no other storm drain connected.</td>
</tr>
<tr>
<td>Life Cycle Cost:</td>
<td>Cost based on the total cost incurred over the system life including research, development, testing, production, construction, operation, and maintenance. Costs are normally determined on present worth or equivalent annual cost basis.</td>
</tr>
<tr>
<td>Low Entry Elevation:</td>
<td>The elevation in a structure where overbank flooding can enter the structure.</td>
</tr>
<tr>
<td>Lowest Adjacent Grade:</td>
<td>The elevation of the lowest grade adjacent to a structure, where the soil meets the foundation around the outside of the structure (including structural members such as basement walkout, patios, decks, porches, support posts or piers, and rim of the window well.</td>
</tr>
<tr>
<td>Lowest Floor:</td>
<td>Refers to the lowest of the following:</td>
</tr>
<tr>
<td></td>
<td>1. The top of the basement floor;</td>
</tr>
<tr>
<td></td>
<td>2. The top of the garage floor, if the garage is the lowest level of the building;</td>
</tr>
<tr>
<td></td>
<td>3. The top of the first floor of buildings constructed on a slab or of buildings elevated on pilings or constructed on a crawl space with permanent openings; or</td>
</tr>
<tr>
<td></td>
<td>4. The top of the floor level of any enclosure below an elevated building where the walls of the enclosure provide any resistance to the flow of flood waters unless:</td>
</tr>
<tr>
<td></td>
<td>a. The walls are designed to automatically equalize the hydrostatic flood forces on the walls by allowing for the entry and exit of flood waters, by providing a minimum of two opening (in addition to doorways and windows) having a total area of one (1) square foot for every two (2) square feet of enclosed area subject to flooding. The bottom of all such openings shall be no higher than one (1) foot above grade.</td>
</tr>
<tr>
<td></td>
<td>b. Such enclosed space shall be usable only for the parking of vehicles or building access.</td>
</tr>
<tr>
<td>Major Drainage System:</td>
<td>Drainage system carrying runoff from an area of one or more square miles.</td>
</tr>
<tr>
<td>Manhole:</td>
<td>Storm drain structure through which a person may enter to gain access to an underground storm drain or enclosed structure.</td>
</tr>
<tr>
<td>Manning Roughness Coefficient or Manning’s “n” Value:</td>
<td>A dimensionless coefficient (“n”) used in the Manning’s equation to account for channel wall frictional losses in steady uniform flow.</td>
</tr>
<tr>
<td>Measurable storm event:</td>
<td>A precipitation event that results in a total measured precipitation accumulation equal to, or greater than, one-half (0.5) inch of rainfall.</td>
</tr>
<tr>
<td>Media Filtration:</td>
<td>A two-stage constructed treatment system that includes a pretreatment settling basin and filtration bed containing sand or other filter media.</td>
</tr>
</tbody>
</table>
Minimum Control Measure: Minimum measures required by the NPDES Phase II program. The six (6) MCMs are: Public education and outreach, Public participation and involvement, Illicit discharge detection and elimination, Construction site runoff control, Post-construction runoff control, and Pollution prevention and good housekeeping.

Minor Drainage Systems: Drainage system carrying runoff from an area of less than one square mile.

Minor Subdivision: See Subdivision, Minor.

Mulch: A natural or artificial layer of plant residue or other materials covering the land surface, at a uniform density of 70% across the entire disturbed area, which conserves moisture, holds soil in place, aids in establishing plant cover, and minimizes temperature fluctuations.

Multi-Family: Any structure which contains three or more dwelling units. A dwelling unit is any structure, or part of a structure, which is constructed to a house a family.

Municipal Separate Storm Sewer System: An MS4 meets all the following criteria: (1) is a conveyance or system of conveyances owned by the state, county, city, town, or other public entity; (2) discharges to waters of the U.S.; (3) is designed or used for collecting or conveying stormwater; (4) is not a combined sewer; and, (5) is not part of a Publicly Owned Treatment Works (POTW).

Municipal, state, federal, or institutional refueling area: An operating gasoline or diesel fueling area whose primary function is to provide fuel to either municipal, state, federal, or institutional equipment or vehicles.

Mutual Drain: A drain that: (1) Is located on two or more tracts of land that are under different ownership; (2) was established by the mutual consent of all the owners; and (3) was not established under or made subject to any drainage statute.

National Flood Insurance Program (NFIP): The NFIP is a Federal program enabling property owners to purchase flood insurance. The Federal Emergency Management Agency administers the NFIP in communities throughout the United States. The NFIP is based on an agreement between local communities and the Federal government which states that if a community will implement floodplain management measures to reduce future flood risks to new construction and substantially improved structures in flood hazard areas, the Federal government will make flood insurance available within the community as a financial protection against flood losses that do occur.

National Geodetic Vertical Datum of 1929: The nationwide, Federal Elevation datum used to reference topographic elevations to a known value.

National Pollution Discharge Elimination System (NPDES): A permit developed by the U.S. EPA through the Clean Water Act. In Indiana, the permitting process has been delegated to IDEM. This permit covers aspects of municipal stormwater quality.

Natural Drainage: The flow patterns of stormwater run-off over the land in its pre-development state.

Nonagricultural land use: Commercial use of land for the manufacturing and wholesale or retail sale of goods or services, residential or institutional use of land intended primarily to
shelter people, highway use of land including lanes, alleys, and streets, and other land uses not included in agricultural land use.

**Nonpoint Source Pollution:** Pollution that enters a water body from diffuse origins on the watershed and does not result from discernable, confined, or discrete conveyances.

**Normal Depth:** Depth of flow in an open conduit during uniform flow for the given conditions.

**North American Vertical Datum of 1988 (NAVD 1988):** The nationwide, Federal Elevation datum used to reference topographic elevations to a known value.

**Nutrient(s):** (1) A substance necessary for the growth and reproduction of organisms. (2) In water, those substances (chiefly nitrates and phosphates) that promote growth of algae and bacteria.

**Off-site:** Everything not located at or within a particular site.

**Off-site Land Areas:** Those areas that by virtue of existing topography naturally shed surface water onto or through the developing property.

**100-Year Frequency Flood:** See “regulatory flood”.

**On-Site:** Located within the controlled or urbanized area where runoff originates.

**Open Drain:** A natural watercourse or constructed open channel that conveys drainage water.

**Open Space:** Any land area devoid of any disturbed or impervious surfaces created by industrial, commercial, residential, agricultural, or other manmade activities.

**Orifice:** A device which controls the rate of flow from a detention basin.

**Outfall scouring:** The deterioration of a streambed or lakebed from an outfall discharge to an extent that the excessive settling of solid material results and suitable aquatic habitat is diminished.

**Outfall:** The point, location, or structure where a pipe or open drain discharges to a receiving body of water.

**Outlet:** The point of water disposal from a stream, river, lake, tidewater, or artificial drain.

**Overland Flow:** Consists of sheet flow, shallow concentrated flow and channel flow.

**Peak Discharge (or Peak Flow):** The maximum instantaneous flow from a given storm condition at a specific location.

**Percolation:** The movement of water through soil.

**Perennial Stream:** A stream that maintains water in its channel throughout the year.

**Permanent stabilization:** The establishment, at a uniform density of seventy percent (75%) across the disturbed area, of vegetative cover or permanent non-erosive material that will ensure the resistance of the soil to erosion, sliding, or other movement.
<table>
<thead>
<tr>

<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permeability (soil)</td>
<td>The quality of a soil that enables water or air to move through it. Usually expressed in inches per hour or inches per day.</td>
</tr>
<tr>
<td>Pervious</td>
<td>Allowing movement of water.</td>
</tr>
<tr>
<td>Pesticides</td>
<td>Chemical compounds used for the control of undesirable plants, animals, or insects. The term includes insecticides, herbicides, algicides, rodenticides, nematicides, fungicides, and growth regulators.</td>
</tr>
<tr>
<td>pH</td>
<td>A numerical measure of hydrogen ion activity, the neutral point being 7.0. All pH values below 7.0 are acid, and all above 7.0 are alkaline.</td>
</tr>
<tr>
<td>Phasing of construction</td>
<td>Sequential development of smaller portions of a large project site, stabilizing each portion before beginning land disturbance on subsequent portions, to minimize exposure of disturbed land to erosion.</td>
</tr>
<tr>
<td>Phosphorus (available)</td>
<td>Inorganic phosphorus that is readily available for plant growth.</td>
</tr>
<tr>
<td>Piping</td>
<td>The formation of &quot;pipes&quot; by underground erosion. Water in the soil carries the fine soil particles away, and a series of eroded tubes or tunnels develop. These openings will grow progressively larger and can cause a dam failure.</td>
</tr>
<tr>
<td>Planimetric Data</td>
<td>Horizontal measurements involving distances or dimensions on a diagram, map, Plat of Survey or topographic map. Normally in units of feet.</td>
</tr>
<tr>
<td>Plat of Survey</td>
<td>A scaled diagram showing boundaries of a tract of land or subdivision. This may constitute a legal description of the land and be used in lieu of a written description.</td>
</tr>
<tr>
<td>Point Source</td>
<td>Any discernible, confined, and discrete conveyance including but not limited to any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, or container from which pollutants are or maybe discharged (P.L. 92-500, Section 502[14]).</td>
</tr>
<tr>
<td>Pollutant of concern</td>
<td>Any pollutant that has been documented via analytical data as a cause of impairment in any waterbody.</td>
</tr>
<tr>
<td>Porosity</td>
<td>The volume of pore space in soil or rock.</td>
</tr>
<tr>
<td>Porous pavement</td>
<td>A type of infiltration practice to improve the quality and reduce the quantity of storm water run-off via the use of manmade, pervious pavement which allows run-off to percolate through the pavement and into underlying soils</td>
</tr>
<tr>
<td>Private Drain</td>
<td>A drain that: (1) Is located on land owned by one person or by two or more persons jointly; and (2) was not established under or made subject to any drainage statute.</td>
</tr>
<tr>
<td>Professional Engineer</td>
<td>A person licensed under the laws of the State of Indiana to practice professional engineering.</td>
</tr>
<tr>
<td>Programmatic Indicator</td>
<td>Any data collected by an MS4 entity that is used to indicate implementation of one (1) or more minimum control measures.</td>
</tr>
<tr>
<td>Project site owner</td>
<td>The person required to submit a stormwater permit application, and required to comply with the terms of the Ordinance, including a developer or a person who has financial and operational control of construction activities, and project plans</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Project site:</td>
<td>The entire area on which construction activity is to be performed.</td>
</tr>
<tr>
<td>Probable Maximum Flood:</td>
<td>The most severe flood that may be expected from a combination of the most critical meteorological and hydrological conditions that are reasonably possible in the drainage basin. It is used in designing high-risk flood protection works and siting of structures and facilities that shall be subject to almost no risk of flooding. The probable maximum flood is usually much larger that the 100-year flood.</td>
</tr>
<tr>
<td>Publicly Owned Treatment Works (POTW):</td>
<td>A municipal operation that breaks down and removes contaminants in the wastewater prior to discharging to a stream through primary and/or secondary treatment systems.</td>
</tr>
<tr>
<td>Qualified professional:</td>
<td>An individual who is trained and experienced in storm water treatment techniques and related fields as may be demonstrated by state registration, professional certification, experience, or completion of coursework that enable the individual to make sound, professional judgments regarding storm water control or treatment and monitoring, pollutant fate and transport, and drainage planning.</td>
</tr>
<tr>
<td>Radius of Curvature:</td>
<td>Length of radius of a circle used to define a curve.</td>
</tr>
<tr>
<td>Rain garden:</td>
<td>A vegetative practice used to alter impervious surfaces, such as roofs, into pervious surfaces for absorption and treatment of rainfall.</td>
</tr>
<tr>
<td>Rainfall Intensity:</td>
<td>The rate at which rain is falling at any given instant, usually expressed in inches per hour.</td>
</tr>
<tr>
<td>Reach:</td>
<td>Any length of river, channel or storm drain.</td>
</tr>
<tr>
<td>Receiving Stream or Receiving Water:</td>
<td>The body of water into which runoff or effluent is discharged. The term does not include private drains, unnamed conveyances, retention and detention basins, or constructed wetlands used as treatment.</td>
</tr>
<tr>
<td>Recharge:</td>
<td>Replenishment of groundwater reservoirs by infiltration and transmission from the outcrop of an aquifer or from permeable soils.</td>
</tr>
<tr>
<td>Recurrence Interval:</td>
<td>A statistical expression of the average time between floods equaling or exceeding a given magnitude.</td>
</tr>
<tr>
<td>Redevelopment:</td>
<td>Alterations of a property that change a site or building in such a way that there is disturbances of one (1) acre or more of land. The term does not include such activities as exterior remodeling.</td>
</tr>
<tr>
<td>Regulated Area:</td>
<td>All areas within the corporate boundries of the City of Greenfield</td>
</tr>
<tr>
<td>Regulatory or 100-Year Flood:</td>
<td>The discharge or elevation associated with the 100-year flood as calculated by a method and procedure which is acceptable to and approved by the Indiana Department of Natural Resources and the Federal Emergency Management Agency. The &quot;regulatory flood&quot; is also known as the &quot;base flood&quot;.</td>
</tr>
</tbody>
</table>
**Regulatory Floodway:**
See Floodway.

**Release Rate:**
The amount of storm water release from a storm water control facility per unit of time.

**Reservoir:**
A natural or artificially created pond, lake or other space used for storage, regulation or control of water. May be either permanent or temporary. The term is also used in the hydrologic modeling of storage facilities.

**Retail gasoline outlet:**
An operating gasoline or diesel fueling facility whose primary function is the resale of fuels. The term applies to facilities that create five thousand (5,000) or more square feet of impervious surfaces, or generate an average daily traffic count of one hundred (100) vehicles per one thousand (1,000) square feet of land area.

**Retention basin:**
A type of storage practice, that has no positive outlet, used to retain storm water run-off for an indefinite amount of time. Runoff from this type of basin is removed only by infiltration through a porous bottom or by evaporation.

**Retention:**
The storage of stormwater to prevent it from leaving the development site. May be temporary or permanent.

**Retention Facility:**
A facility designed to completely retain a specified amount of stormwater runoff without release except by means of evaporation, infiltration or pumping. The volumes are often referred to in units of acre-feet.

**Return Period:**
The average interval of time within which a given rainfall event will be equaled or exceeded once. A flood having a return period of 100 years has a one percent probability of being equaled or exceeded in any one year.

**Revetment:**
Facing of stone or other material, either permanent or temporary, placed along the edge of a stream to stabilize the bank and protect it from the erosive action of the stream.

**Revetment Riprap:**
Material graded such that: (1) no individual piece weighs more than 120 lbs. and (2) 90-100% will pass through a 12-inch sieve, 20-60% through a 6-inch sieve, and not more than 10% through a 12-inch sieve.

**Right-of-Way for a County Drain:**
The statutory right of way as defined by Indiana Code for a regulated drain.

**Riparian habitat:**
A land area adjacent to a waterbody that supports animal and plant life associated with that waterbody.

**Riparian zone:**
Of, on, or pertaining to the banks of a stream, river, or pond.

**Riprap:**
Broken rock, cobble, or boulders placed on earth surfaces, such as the face of a dam or the bank of a stream, for protection against the action of water (waves).

**River Restoration:**
Restoring the channel of a stream or ditch to its perceived original, non-obstructed capacity by means of clearing & snagging, obstruction removal, and inexpensive streambank protection measures. The term "restoration", as noted, does not necessarily imply restoration or improvement of water quality or habitat within the channel or its adjacent area.
Riverine: Relating to, formed by, or resembling a stream (including creeks and rivers)

Runoff Coefficient: A decimal fraction relating the amount of rain which appears as runoff and reaches the storm drain system to the total amount of rain falling. A coefficient of 0.5 implies that 50 percent of the rain falling on a given surface appears as storm water runoff.

Runoff: That portion of precipitation that flows from a drainage area on the land surface, in open channels, or in stormwater conveyance systems.

Sand: (1) Soil particles between 0.05 and 2.0 mm in diameter. (2) A soil textural class inclusive of all soils that are at least 70% sand and 15% or less clay.

Sanitary Backup: The condition where a sanitary sewer reaches capacity and surcharges into the lowest area

Scour: The clearing and digging action of flowing water.

Sediment: Solid material (both mineral and organic) that is in suspension, is being transported, or has been moved from its site of origin by air, water, gravity, or ice and has come to rest on the earth’s surface.

Sediment Forebay: A small pond placed in front of a larger retention/detention structure such as a wet pond, dry pond, or wetland to intercept and concentrate a majority of sediment that is coming into the system before it reaches the larger structure.

Sedimentation: The process that deposits soils, debris and other unconsolidated materials either on the ground surfaces or in bodies of water or watercourses.

Seepage: The passage of water or other fluid through a porous medium, such as the passage of water through an earth embankment or masonry wall.

Sensitive Water: A water body in need of priority protection or remediation base on its:

- providing habitat for threatened or endangered species,
- usage as a public water supply intake,
- relevant community value,
- usage for full body contact recreation,
- exceptional use classification as found in 327 IAC 2-1-11(b), outstanding state resource water classification as found in 327 IAC 2-1-2(3) and 327 IAC 2-1.5-19(b).

Settling Basin: An enlargement in the channel of a stream to permit the settling of debris carried in suspension.

Silt Fence: A fence constructed of wood or steel supports and either natural (e.g. burlap) or synthetic fabric stretched across area of non-concentrated flow during site development to trap and retain on-site sediment due to rainfall runoff.

Silt: (1) Soil fraction consisting of particles between 0.002 and 0.05 mm in diameter. (2) A soil textural class indicating more than 80% silt.

Siphon: A closed conduit or portion of which lies above the hydraulic grade line,
resulting in a pressure less than atmospheric and requiring a vacuum within the conduit to start flow. A siphon utilizes atmospheric pressure to effect or increase the flow of water through a conduit. An inverted siphon is used to carry storm water flow under an obstruction such as a sanitary sewer.

**Site:**
The entire area included in the legal description of the land on which land disturbing activity is to be performed.

**Slope:**
Degree of deviation of a surface from the horizontal, measured as a numerical ratio or percent. Expressed as a ratio, the first number is commonly the horizontal distance (run) and the second is the vertical distance (rise)—e.g., 2:1. However, the preferred method for designation of slopes is to clearly identify the horizontal (H) and vertical (V) components (length (L) and Width (W) components for horizontal angles). Also note that according to international standards (Metric), the slopes are presented as the vertical or width component shown on the numerator—e.g., 1V:2H. Slope expressions in the Ordinance follow the common presentation of slopes—e.g., 2:1 with the metric presentation shown in parenthesis—e.g., (1V:2H). Slopes can also be expressed in "percents". Slopes given in percents are always expressed as (100*V/H) —e.g., a 2:1 (1V:2H) slope is a 50% slope.

**Soil and Water Conservation District:**
A public organization created under state law as a special-purpose district to develop and carry out a program of soil, water, and related resource conservation, use, and development within its boundaries. A subdivision of state government with a local governing body, established under IC 14-32.

**Soil:**
The unconsolidated mineral and organic material on the immediate surface of the earth that serves as a natural medium for the growth of land plants.

**Solid Waste:**
Any garbage, refuse, debris, or other discarded material.

**Special Flood Hazard Area:**
An area that is inundated during the 100-Year flood.

**Spill:**
The unexpected, unintended, abnormal, or unapproved dumping, leakage, drainage, seepage, discharge, or other loss of petroleum, hazardous substances, extremely hazardous substances, or objectionable substances. The term does not include releases to impervious surfaces when the substance does not migrate off the surface or penetrate the surface and enter the soil.

**Spillway:**
A waterway in or about a hydraulic structure, for the escape of excess water.

**Standard Project Flood:**
A term used by the U.S. Army Corps of Engineers to designate a flood that may be expected from the most severe combination of meteorological and hydrological conditions that are considered reasonable characteristics of the geographical area in which the drainage basin is located, excluding extremely rare combinations. The peak flow for a standard project flood is generally 40 – 60 percent of the probable maximum flood for the same location.

**Stilling Basin:**
A basin used to slow water down or dissipate its energy.

**Storage practices:**
Any structural BMP intended to store or detain stormwater and slowly release it to receiving waters or drainage systems. The term includes detention and retention basins.

**Storm drain signing:**
Any marking procedure that identifies a storm sewer inlet as draining directly to
a receiving waterbody so as to avoid dumping pollutants. The procedures can include painted or cast messages and adhesive decals.

**Storm Duration:** The length of time that water may be stored in any stormwater control facility, computed from the time water first begins to be stored.

**Storm Event** An estimate of the expected amount of precipitation within a given period of time. A 10-yr. frequency, 24-hr. duration storm event, for example, is a storm that has a 10% probability of occurring in any one year. Precipitation is measured over a 24-hr. period.

**Storm Frequency** The time interval between major storms of predetermined intensity and volumes of runoff (e.g. a 5-yr., 10-yr., or 20-yr. storm).

**Storm Sewer** A closed conduit for conveying collected storm water, while excluding sewage and industrial wastes. Also called a storm drain.

**Stormwater** Water resulting from rain, melting or melted snow, hail, or sleet

**Stormwater Drainage System** All means, natural or man-made, used for conducting storm water to, through or from a drainage area to any of the following: conduits and appurtenant features, canals, channels, ditches, storage facilities, swales, streams, culverts, streets and pumping stations.

**Stormwater Facility** All ditches, channels, conduits, levees, ponds, natural and manmade impoundments, wetlands, tiles, swales, sewers and other natural or artificial means of draining surface and subsurface water from land.

**Stormwater Pollution Prevention Plan** A plan developed to minimize the impact of storm water pollutants resulting from construction activities.

**Stormwater Quality Management Plan** A comprehensive written document that addresses stormwater runoff quality.

**Stormwater Quality Measure** A practice, or a combination of practices, to control or minimize pollutants associated with storm water runoff.

**Stormwater runoff** The water derived from rains falling within a tributary basin, flowing over the surface of the ground or collected in channels or conduits.

**Stream** See Intermittent stream, Perennial stream, Receiving stream.

**Streambanks** The usual boundaries (not the flood boundaries) of a stream channel. Right and left banks are named facing downstream.

**Stream Gaging** The quantitative determination of streamflow using gauges, current meters, weirs, or other measuring instruments at selected locations (see Gaging Station).

**Stream Length** The length of a stream or ditch, expressed in miles, from the confluence of the stream or ditch with the receiving stream to the upstream extremity of the stream or ditch, as indicated by the solid or dashed, blue or purple line depicting the stream or ditch on the most current edition of the seven and one-half (72) minute topographic quadrangle map published by the United States Geological Survey, measured along the meanders of the stream or ditch as depicted on the map.

**Strip development** A multi-lot project where building lots front on an existing road.
<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Structure</strong></td>
<td>Refers to a structure that is principally above ground and is enclosed by walls and a roof. The term includes but is not limited to, a gas or liquid storage tank, a manufactured home or a prefabricated building, and recreational vehicles to be installed on a site for more than 180 days.</td>
</tr>
<tr>
<td><strong>Structural Engineer</strong></td>
<td>A person licensed under the laws of the State of Indiana to engage in the designing or supervising of construction, enlargement or alteration of structures or any part thereof.</td>
</tr>
<tr>
<td><strong>Structural Floodplain Management Measures</strong></td>
<td>Those physical or engineering measures employed to modify the way floods behave, (e.g., dams, dikes, levees, channel enlargements and diversions).</td>
</tr>
<tr>
<td><strong>Subarea</strong></td>
<td>Portion of a watershed divided into homogenous drainage units which can be modeled for purposes of determining runoff rates. The subareas have distinct boundaries, as defined by the topography of the area.</td>
</tr>
<tr>
<td><strong>Subbasin</strong></td>
<td>Portion of a watershed divided into homogenous drainage units which can be modeled for purposes of determining runoff rates. The subareas have distinct boundaries, as defined by the topography of the area.</td>
</tr>
<tr>
<td><strong>Subdivision</strong></td>
<td>Any land that is divided or proposed to be divided into lots, whether contiguous or subject to zoning requirements, for the purpose of sale or lease as part of a larger common plan of development or sale.</td>
</tr>
<tr>
<td><strong>Subdivision, Minor</strong></td>
<td>The subdivision of a parent parcel into any combination of not more than three (3) contiguous or non-contiguous new residential, commercial, or industrial building sites. The parcel shall front upon an existing street which is an improved right-of-way maintained by the County or other governmental entity and not involve any new street.</td>
</tr>
<tr>
<td><strong>Subsoil</strong></td>
<td>The B horizon of soils with distinct profiles. In soils with weak profile development, the subsoil can be defined as the soil below which roots do not normally grow.</td>
</tr>
<tr>
<td><strong>Subsurface Drain</strong></td>
<td>A pervious backfield trench, usually containing stone and perforated pipe, for intercepting groundwater or seepage</td>
</tr>
<tr>
<td><strong>Subwatershed</strong></td>
<td>A watershed subdivision of unspecified size that forms a convenient natural unit. See also Subarea.</td>
</tr>
<tr>
<td><strong>Sump Failure</strong></td>
<td>A failure of the sump pump that results in inundation of crawl space or basement.</td>
</tr>
<tr>
<td><strong>Sump Pump</strong></td>
<td>A pump that discharges seepage from foundation footing drains.</td>
</tr>
<tr>
<td><strong>Surcharge</strong></td>
<td>Backup of water in a sanitary or storm sewer system in excess of the design capacity of the system.</td>
</tr>
<tr>
<td><strong>Surface Runoff</strong></td>
<td>Precipitation that flows onto the surfaces of roofs, streets, the ground, etc., and is not absorbed or retained by that surface but collects and runs off.</td>
</tr>
<tr>
<td><strong>Suspended Solids</strong></td>
<td>Solids either floating or suspended in water.</td>
</tr>
<tr>
<td><strong>Swale</strong></td>
<td>An elongated depression in the land surface that is at least seasonally wet, is usually heavily vegetated, and is normally without flowing water. Swales</td>
</tr>
</tbody>
</table>
conduct stormwater into primary drainage channels and may provide some groundwater recharge.

**Tailwater**

The water surface elevation at the downstream side of a hydraulic structure (i.e. culvert, bridge, weir, dam, etc.).

**Temporary Stabilization**

The covering of soil to ensure its resistance to erosion, sliding, or other movement. The term includes vegetative cover, anchored mulch, or other non-erosive material applied at a uniform density of seventy percent (70%) across the disturbed area.

**Thalweg**

The deepest point (or centerline) of a channel.

**Tile Drain**

Pipe made of perforated plastic, burned clay, concrete, or similar material, laid to a designed grade and depth, to collect and carry excess water from the soil.

**Tile Drainage**

Land drainage by means of a series of tile lines laid at a specified depth, grade, and spacing.

**Time of Concentration (tc)**

The travel time of a particle of water from the most hydraulically remote point in the contributing area to the point under study. This can be considered the sum of an overland flow time and times of travel in street gutters, storm sewers, drainage channels, and all other drainage ways.

**Topographic Map**

Graphical portrayal of the topographic features of a land area, showing both the horizontal distances between the features and their elevations above a given datum.

**Topography**

The representation of a portion of the earth's surface showing natural and man-made features of a given locality such as rivers, streams, ditches, lakes, roads, buildings and most importantly, variations in ground elevations for the terrain of the area.

**Topsoil**

(1) The dark-colored surface layer, or a horizon, of a soil; when present it ranges in depth from a fraction of an inch to 2-3 ft. (2) Equivalent to the plow layer of cultivated soils. (3) Commonly used to refer to the surface layer(s), enriched in organic matter and having textural and structural characteristics favorable for plant growth.

**Total Maximum Daily Load**

Method used to establish allowable loadings for specified pollutants in a surface water resource to meet established water quality standards.

**Toxicity**

The characteristic of being poisonous or harmful to plant or animal life. The relative degree or severity of this characteristic.

**TP-40 Rainfall**

Design storm rainfall depth data for various durations published by the National Weather Service in their Technical Paper 40 dated 1961.

**Trained individual**

An individual who is trained and experienced in the principles of storm water quality, including erosion and sediment control as may be demonstrated by state registration, professional certification, experience, or completion of coursework that enable the individual to make judgments regarding storm water control or treatment and monitoring.

**Transition Section**

Reaches of the stream of floodway where water flows from a narrow cross-section to a wide cross-section or vice-versa.
Tributary: Based on the size of the contributing drainage area, a smaller watercourse which flows into a larger watercourse.

Turbidity: (1) Cloudiness of a liquid, caused by suspended solids. (2) A measure of the suspended solids in a liquid.

Underdrain: A small diameter perforated pipe that allows the bottom of a detention basin, channel or swale to drain.

Unified Soil Classification System: A system of classifying soils that is based on their identification according to particle size, gradation, plasticity index, and liquid limit.

Uniform Flow: A state of steady flow when the mean velocity and cross-sectional area remain constant in all sections of a reach.

Unit Hydrograph: The hydrograph that results from one inch of precipitation excess generated uniformly over the watershed at a uniform rate during a specified period of time.

Urban Drain: A drain defined as “Urban Drain” in Indiana Drainage Code.

Urbanization: The development, change or improvement of any parcel of land consisting of one or more lots for residential, commercial, industrial, institutional, recreational or public utility purposes.

Vegetated swale: A type of vegetative practice used to filter stormwater runoff via a vegetated, shallow-channel conveyance.

Vegetative practices: Any nonstructural or structural BMP that, with optimal design and good soil conditions, utilizes various forms of vegetation to enhance pollutant removal, maintain and improve natural site hydrology, promote healthier habitats, and increase aesthetic appeal. Examples include grass swales, filter strips, buffer strips, constructed wetlands, and rain gardens.

Vegetative Stabilization: Protection of erodible or sediment producing areas with: permanent seeding (producing long-term vegetative cover), short-term seeding (producing temporary vegetative cover), or sodding (producing areas covered with a turf of perennial sod-forming grass).

Water Course: Any river, stream, creek, brook, branch, natural or man-made drainage way in or into which stormwater runoff or floodwaters flow either continuously or intermittently.

Water Quality: A term used to describe the chemical, physical, and biological characteristics of water, usually in respect to its suitability for a particular purpose.

Water Resources: The supply of groundwater and surface water in a given area.

Water Table: (1) The free surface of the groundwater. (2) That surface subject to atmospheric pressure under the ground, generally rising and failing with the season or from other conditions such as water withdrawal.

Waterbody: Any accumulation of water, surface, or underground, natural or artificial.

Watercourse: Any river, stream, creek, brook, branch, natural or man-made drainageway in or into which stormwater runoff or floodwaters flow either continuously or
intermittently.

**Watershed Area**

- All land and water within the confines of a drainage divide. See also Watershed.

**Watershed**

- The region drained by or contributing water to a specific point that could be along a stream, lake or other stormwater facilities. Watersheds are often broken down into subareas for the purpose of hydrologic modeling.

**Waterway**

- A naturally existing or manmade open conduit or channel utilized for the conveyance of water.

**Weir**

- A channel-spanning structure for measuring or regulating the flow of water.

**Wellhead protection area**

- Has the meaning set forth in 327 IAC 8-4.1-1(27).

**Wet-Bottom Detention Basin**

- (Retention Basin)

- A basin designed to retain a permanent pool of water after having provided its planned detention of runoff during a storm event.

**Wet Pond**

- A constructed basin that has a permanent pool of water throughout the year (or at least throughout the wet season). Ponds treat incoming stormwater runoff by allowing particles to settle and algae to take up nutrients.

**Wetlands**

- Areas that are inundated or saturated by surface water or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions.
APPENDIX B

Applications, Forms and Miscellaneous Sheets required to Comply with the City of Greenfield Stormwater Management Ordinance

B1 – Conceptual Drainage Plan Review Forms
   Conceptual Drainage Plan Review Application

B2 – Stormwater Permit Forms
   Stormwater Permit Application
   Notice of Intent – State Form #47487
   Statement of Financial Responsibility
   Stormwater Permit Application Check-In Checklist

B3 – Construction Inspection/Completion Forms
   Construction Site Inspection and Maintenance Log
   Certification of Completion & Compliance
   Notice of Termination – State Form #51514
   Notice of Termination Inspection

B4 – Individual Residential Lot Permit Forms
   Instructions for Residential Plot Plan Permit Request
   Residential Lot Plot Plan Permit Request Application
   Individual Lot Typical Erosion & Sediment Control Plan and Certification

B5 – Post-Construction Maintenance and Inspections Forms
   Post-Construction BMP Inspection Checklists
B1 – Conceptual Drainage Plan Review Forms

#### 1. Application Fee

Check Attached.

#### 2. Letter of Intent

Letter of Intent for obtaining any needed consents, off-site easements, or right-of-way.

#### 3. Project Narrative and Supporting Documents

- Description of the nature and purpose of the project.
- General description of the existing and proposed drainage systems in narrative form.
- General description of regulated drains, farm drains, inlets and outfalls in narrative form, if any of record.
- General description of all existing storm, sanitary, combined sewer, and septic tank systems and outfalls in narrative form.
- Vicinity map depicting the project site location in relation to recognizable local landmarks, Citys, and major roads, such as a USGS topographic quadrangle map or county or municipal road map.
- A map showing the location, name, and normal water level of all wetlands, lakes, ponds, and water courses on or adjacent to the project site.
- A map showing one hundred (100) year floodplains, floodway fringes, and floodways. Please note if none exists.
- A map showing watershed boundaries with USGS contours or best information possible.
- A map showing existing watercourse or regulated drains.

#### 4. Conceptual Plans

Two (2) complete sets of conceptual plans showing general project layout, including existing and proposed drainage systems and proposed outlets (plan sheets must be larger than 11” by 17”, but not to exceed 24” by 36”).

<td>Date Completed:</td>
</tr>
</tbody>
</table>

#### 1. Application Fee

- Check Attached

#### 2. Notice of Intent

- Completed Notice of Intent -- State Form #47487

#### 3. Construction Plans

- Title sheet which includes location map, vicinity map, operating authority, design company name, developer name, and index of plan sheets.

- A copy of a legal boundary survey for the site, performed in accordance with Rule 12 of Title 865 of the Indiana Administrative Code or any applicable and subsequently adopted rule or regulation for the subdivision limits, including all drainage easements and wetlands.

- A reduced plat or project site map showing the parcel identification numbers, the lot numbers, lot boundaries, easements, and road layout and names. The reduced map must be legible and submitted on a sheet or sheets no larger than eleven (11) inches by seventeen (17) inches for all phases or sections of the project site.

- An existing project site layout that must include the following information:

  **A topographic map of the land to be developed and such adjoining land whose topography may affect the layout or drainage of the development.** The contour intervals shall be one (1) foot when slopes are less than or equal to two percent (<2%) and shall be two (2) feet when slopes exceed two percent (>2%). All elevations shall be given in either National Geodetic Vertical Datum of 1929 (NGVD) or North American Vertical Datum of 1988 (NAVD). The horizontal datum of topographic map shall be based on Indiana State Plane Coordinates, NAD83. The map will contain a notation indicating these datum information.

  a) If the project site is less than or equal to two (2) acres in total land area, the topographic map shall include all topography of land surrounding the site to a distance of at least one hundred (100) feet.

  b) If the project site is greater than two (2) acres in total land area, the topographic map shall include all topography of land surrounding the site to a distance of at least two hundred (200) feet.

- Location, name, and normal water level of all wetlands, lakes, ponds, and water courses on or adjacent to the project site.

- Location of all existing structures on the project site.

- One hundred (100) year floodplains, floodway fringes, and floodways. Please note if none exists.

- Identification and delineation of vegetative cover such as grass, weeds, brush, and trees on the project site.

- Location of storm, sanitary, combined sewer, and septic tank systems and outfalls.

- Land use of all adjacent properties.

- Identification and delineation of sensitive areas.

- The location of regulated drains, farm drains, inlets and outfalls, if any of record.

- Location of all existing cornerstones within the proposed development and a plan to protect and preserve them.

- A grading and drainage plan, including the following information:
All information from the existing site layout items listed above
Location of all proposed site improvements, including roads, utilities, lot delineation and identification, proposed structures, and common areas.

One hundred (100) year floodplains, floodway fringes, and floodways. Please note if none exists.
Delineation of all proposed land disturbing activities, including off-site activities that will provide services to the project site.

Information regarding any off-site borrow, stockpile, or disposal areas that are associated with a project site, and under the control of the project site owner.
Existing and proposed topographic information at a contour interval appropriate to indicate drainage patterns.

Location, size, and dimensions of all existing streams to be maintained, and new drainage systems such as culverts, bridges, storm sewers, conveyance channels, and 100-year overflow paths/ponding areas shown as hatched areas, along with the associated easements.
Pipes and associated structures data, including sizes, lengths, and material

Location, size, and dimensions of features such as permanent retention or detention facilities, including existing or manmade wetlands, used for the purpose of stormwater management. Include existing retention or detention facilities that will be maintained, enlarged, or otherwise altered and new ponds or basins to be built.

Emergency flood routing path(s) and their invert elevations from detention facilities to the receiving system

One or more typical cross sections of all existing and proposed channels or other open drainage facilities carried to a point above the 100-year high water and showing the elevation of the existing land and the proposed changes, together with the high water elevations expected from the 100 year storm under the controlled conditions called for by the ordinance, and the relationship of structures, streets, and other facilities

A drainage summary, which summarizes the basic conditions of the drainage design, including site acreage, off-site/upstream acreage, allowable release rates, post-developed 10-year, and 100-year flows leaving the site, volume of detention required, volume of detention provided, and any release rate restrictions

Arrows designating the direction of stormwater runoff

Spot elevations appropriate to define elevations

Utility plan sheet(s) showing the location of all existing and proposed utility lines for the project, including all available information related to the utilities, such as pipe size and material, and invert elevations

Storm sewer plan/profile sheet(s) at a scale of 5 vertical and 50 horizontal showing the elevation, size, length, location of al proposed storm sewers. Existing and proposed ground grades, storm sewer structures elevations, and utility crossings also must be included. The actual correct datum (not an assumed one) must be used for the profile sheets and all pipe inverts, top of casting elevations, casting types, structure numbers, and pipe slopes clearly labeled.

A 24-inch by 36-inch plat on the same sheet size used for recording, including the following information:

- Legal description.
- Cross reference to Rule 12.
- Regulated drain statement and table.
- Proposed subdivision landscape plans
- A copy of the subdivision covenants

Any other information required by the City Engineer in order to thoroughly evaluate the submitted material.

A summary report, including the following information:
- Description of the nature and purpose of the project.
- The significant drainage problems associated with the project.
- The analysis procedure used to evaluate these problems and to propose solutions.
Any assumptions or special conditions associated with the use of these procedures, especially the hydrologic or hydraulic methods.

The proposed design of the drainage control system.

The results of the analysis of the proposed drainage control system showing that it does solve the project’s drainage problems and that it meets the requirements of the ordinance and these standards. This must include a table summarizing, for each eventual site outlet, the pre-developed acreage tributary to each eventual site outlet, the unit discharge allowable release rate used, the resulting allowable release rate in cfs for the post-developed 10-year and 100-year events, pre-developed 2-year flow rates in cfs as well as pre- and post-developed flow rates for 10- and 100-year events. The worksheet provided in the City of Greenfield Stormwater Technical Standards Manual as Table 6-1 should be filled and submitted as part of the report. Any hydrologic or hydraulic calculations or modeling results must be adequately cited and described in the summary description. If hydrologic or hydraulic models are used, the input and output files for all necessary runs must be included in the appendices. A map showing any drainage area subdivisions used in the analysis must accompany the report.

Soil properties, characteristics, limitations, and hazards associated with the project site and the measures that will be integrated into the project to overcome or minimize adverse soil conditions.

A narrative and photographic record of the condition of the downstream receiving system

Identification of any other state or federal water quality permits that are required for construction activities associated with the owner’s project site.

Proof of Errors and Omissions Insurance for the registered professional engineer or licensed surveyor showing a minimum amount of $1,000,000 in coverage.

A Hydrologic/Hydraulic Analysis, consistent with the methodologies and calculation included in the [technical standards], and including the following information:

A hydraulic report detailing existing and proposed drainage patterns on the subject site. The report should include a description of present land use and proposed land use. Any off-site drainage entering the site should be addressed as well. This report should be comprehensive and detail all of the steps the engineer took during the design process.

All hydrologic and hydraulic computations must be included in the submittal. These calculations must include, but are not limited to: runoff curve numbers and runoff coefficients, runoff calculations, stage-discharge relationships, times-of-concentration and storage volumes.

Copies of all computer runs. These computer runs must include both the input and the outputs. Electronic copies of the computer runs with input files will expedite the review process and is required to be submitted.

A set of exhibits must be included showing the drainage sub-areas and a schematic detailing of how the computer models were set up.

A conclusion which summarizes the hydraulic design and details how this design satisfies the Ordinance.

5. Stormwater Pollution Prevention Plan for Construction Sites

Location, dimensions, detailed specifications, and construction details of all temporary and permanent stormwater quality measures.

Soil map of the predominant soil types, as determined by the United States Department of Agriculture (USDA), Natural Resources Conservation Service (NRCS) Soil Survey, or as determined by a soil scientist. Hydrologic classification for soils should be shown when hydrologic methods requiring soils information are used. A soil legend must be included with the soil map.

14-Digit Watershed Hydrologic Unit Code.

An estimate of the peak discharge, based on the ten (10) year storm event, of the project site for post-construction conditions.

Locations where stormwater may be directly discharged into groundwater, such as abandoned wells or sinkholes. Please note if none exists.

Locations of specific points where stormwater discharge will leave the project site.

Name of all receiving waters. If the discharge is to a separate municipal storm sewer, identify the name of
6. Post-Construction Storm Water Pollution Prevention Plan

- A description of potential pollutant sources from the proposed land use, which may reasonably be expected to add a significant amount of pollutants to stormwater discharges.
- Location, dimensions, detailed specifications, and construction details of all post-construction stormwater quality measures.
- A description of measures that will be installed to control pollutants in stormwater discharges that will occur after construction activities have been completed. Such practices include infiltration of run-off, flow reduction by use of open vegetated swales and natural depressions, buffer strip and riparian zone preservation, filter strip creation, minimization of land disturbance and surface imperviousness, maximization of open space, and stormwater retention and detention ponds.
- A sequence describing when each post-construction stormwater quality measure will be installed.
- Stormwater quality measures that will remove or minimize pollutants from stormwater run-off.
- Stormwater quality measures that will be implemented to prevent or minimize adverse impacts to stream and riparian habitat.
- An operation and maintenance manual for all post-construction stormwater quality measures to facilitate their proper long term function. This operation and maintenance manual shall be made available to future parties who will assume responsibility for the operation and maintenance of the post-construction stormwater quality measures. The manual shall include the following:
  - Contact information for the BMP owner (i.e. name, address, business phone number, cell phone number, pager number, e-mail address, etc.).
  - A statement that the BMP owner is responsible for all costs associated with maintaining the BMP.
  - A right-of-entry statement allowing City personnel to inspect and maintain the BMP.
  - Specific actions to be taken regarding routine maintenance, remedial maintenance of structural components, and sediment removal. Sediment removal procedures should be explained in both narrative and graphical forms. A tabular schedule should be provided listing all maintenance activities and dates for performing these required maintenance activities.
  - Site drawings showing the location of the BMP and access easement, cross sections of BMP features (i.e. pond, forebay(s), structural components, etc.), and the point of discharge for stormwater treated by the BMP. These drawings need to be submitted both in hard copy and in digital format acceptable to the City of Greenfield.

7. Stormwater Permit Check-in Checklist

- Must be completed and all items listed must be provided at project submittal.
Submission of this Notice of Intent letter constitutes notice that the project site owner is applying for coverage under the National Pollutant Discharge Elimination System (NPDES) General Permit Rule for Storm Water Discharges Associated with Construction Activity. Permitted project site owners are required to comply with all terms and conditions of the General Permit Rule 327 IAC 15-5 (Rule 5).

Check the type of Submittal:  □ Initial  □ Amendment  □ Renewal  □ Extension

Project Name and Location:
Project Permit # ______________ Project Name: ___________________________________________ County: _______________ Brief Description of Project Location: _____________________________________________________________

Latitude ____________________________ and Longitude ____________________________ Quarter _____________ Section ____________ Township____________ Range_____________

Does □ all or □ part of this project lie within the jurisdictional boundaries of a Municipal Separate Storm Sewer System (MS4) as defined in 327 IAC 15-13?  □ Yes  □ No  If yes, please name the MS4(s):

Project Site Owner and Project Contact Information:

Timetable (Maximum of 5 Years):
Start Date: ________________ and Estimated End Date for all Land Disturbing Activity: ________________

(Continued on Reverse Side)
Construction Plan Certification:
By signing this Notice of Intent letter, I certify the following:

A. The storm water quality measures included in the Construction Plan comply with the requirements of 327 IAC 15-5-6.5, 327 IAC 15-5-7, and 327 IAC 15-5-7.5;

B. the storm water pollution prevention plan complies with all applicable federal, state, and local storm water requirements;

C. the measures required by section 7 and 7.5 of this rule will be implemented in accordance with the storm water pollution prevention plan;

D. if the projected land disturbance is One (1) acre or more, the applicable Soil and Water Conservation District or other entity designated by the Department, has been sent a copy of the Construction Plan for review;

E. storm water quality measures beyond those specified in the storm water pollution prevention plan will be implemented during the life of the permit if necessary to comply with 327 IAC 15-5-7; and

F. implementation of storm water quality measures will be inspected by trained individuals.

In addition to this form, I have enclosed the Following:
- Verification by the reviewing agency of acceptance of the Construction Plan.
- Proof of publication in a newspaper of general circulation in the affected area that notified the public that a construction activity is to commence, including all required elements contained in 327 IAC 15-5-5 (9).

- $100 check or money order payable to the Indiana Department of Environmental Management. If the project lies solely within the permitted jurisdiction of an MS4 and is regulated by the MS4 under 327 IAC 15-13 – a fee is not required with submittal of this Notice of Intent.

A permit issued under 327 IAC 15-5 is granted by the commissioner for a period of five (5) years from the date coverage commences. Once the five (5) year permit term duration is reached, a general permit issued under this rule will be considered expired, and, as necessary for construction activity continuation, a new Notice of Intent letter would need to be submitted ninety (90) days prior to the termination of coverage.

Project Site Owner Responsibility Statement:
By signing this Notice of Intent letter, I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information or violating the provisions of 327 IAC 15-5, including the possibility of fine and imprisonment for knowing violations.

Printed Name of Project Owner__________________________________________________________

Signature of Project Owner __________________________ Date: ___________________

This Notice of Intent must be signed by an individual meeting the signatory requirements in 327 IAC 15-4-3(g)

Mail this form to: Indiana Department of Environmental Management
Office of Water Quality, Storm Water (Rule 5) Desk
100 North Senate Avenue, P.O. Box 6015
Indianapolis, IN 46206-6015

327 IAC 15-5-6 (a) also requires a copy of the completed Notice of Intent letter be submitted to the local Soil and Water Conservation District or other entity designated by the Department, where the land disturbing activity is to occur.

Questions regarding the development of the Construction Plan and/or field implementation of 327 IAC 15-5 may be directed to your local Soil and Water Conservation District office or the Department of Natural Resources at 317-233-3870. Questions regarding the Notice of Intent may be directed to the Rule 5 contact person at 317/233-1864 or 800/451-6027 ext 31864.

B3 – Construction Inspection/Completion Forms

Construction Site Inspection and Maintenance Log
Certification of Completion & Compliance
Notice of Termination – State Form #51514
Notice of Termination Inspection
CONSTRUCTION SITE INSPECTION AND MAINTENANCE LOG
(To be Completed by Property Owner or Agent)

All stormwater pollution prevention BMPs shall be inspected and maintained as needed to ensure continued performance of their intended function during construction and shall continue until the entire site has been stabilized and a Notice of Termination has been issued. An inspection of the project site must be completed by the end of the next business day following each measurable storm event. If there are no measurable storm events within a given week, the site should be monitored at least once in that week. Maintenance and repair shall be conducted in accordance with the accepted site plans. This log shall be kept as a permanent record and must be made available upon inspection, in an organized fashion, within forty-eight (48) hours upon request.

Certification of Completion & Compliance

CERTIFICATE OF COMPLETION & COMPLIANCE

Address of premises on which land alteration was accomplished: ______________________________________
_________________________________________________________________________________________
_________________________________________________________________________________________

Inspection Date(s): ______________________  Permit Number: _________________________________
Relative to plans prepared by: _________________________ on ________________________________ (date)

I hereby certify that:

1. I am familiar with drainage requirements applicable to such land alteration (as set forth in the
   Stormwater Management Ordinance of City of Greenfield); and

2. I (or a person under my direct supervision) have personally inspected the completed work and
   examined the drainage permit and its conditions, as-built plans, and final drainage calculations
   consistent with as-built conditions performed pursuant to the above referenced drainage
   permit; and

3. To the best of my knowledge, information, and belief, such land alteration has been performed and
   completed in conformity with all such drainage requirements, except ______________________

RULE 5 –
Notice of Termination (NOT)
Storm Water Runoff Associated with Construction Activity
NPDES General Permit Rule 327 IAC 15-5 (Rule 5)

State Form 51514 (R / 1-04)

INDIANA DEPARTMENT OF ENVIRONMENTAL MANAGEMENT

NOTE:
- This Notice of Termination must be signed by an individual meeting the signatory requirements in 327 IAC 15-4-3(g).
- Please submit the completed Notice of Termination form to the SWCD, DNR-DSC, or other Entity Designated by the Department as the reviewing agency. The request for termination will be reviewed for concurrence and either returned to the Project Site Owner or forwarded to the IDEM.

Submission of this Notice of Termination letter constitutes notice to the Commissioner that the project site owner is applying for Termination of Coverage under the National Pollutant Discharge Elimination System (NPDES) General Permit Rule for Storm Water Discharges Associated with Construction Activity.

Project Name and Location:
Permit Number: ____________________________
Project Name: ____________________________ County: ____________________________
Company Name (If Applicable):
Project Site Owner’s Name (An Individual):
Address:
City: ____________________________ State: ____________________________ Zip: ____________________________
Phone: ____________________________ FAX: ____________________________ E-Mail Address (If Available):

This Notice of Termination is Being Submitted for the Following:

Select one of the three Options that apply to Permit Termination by checking the appropriate box, complete all information associated with that option, and complete the “Project Site Owner Responsibility Statement”.

Option # 1
☐ Certification for Change of Ownership:
(Does not Apply to the Sale of Individual lots within the Permitted Acreage; only the Sale of the Entire Project Site as Originally Permitted)

By Signing this Notice of Termination, I Certify the Following:
A. The project was sold; I am no longer the project site owner as was designated in my Notice of Intent. The new owner of the project site is:
   Company Name (If Applicable):
   Project Site Owner’s Name (An Individual):
   Address:
   City: ____________________________ State: ____________________________ Zip: ____________________________
   Phone: ____________________________ FAX: ____________________________ E-Mail Address (If Available):
B. I have notified the new Project Site Owner of his/her responsibilities to comply with 327 IAC 15-5 and the requirements associated with the rule including filing a new Notice of Intent.

For questions regarding this form, contact:
IDEM – Rule 5 Coordinator
100 North Senate Avenue, Rm 1255
P.O. Box 6015
Indianapolis, IN 46206-6015
Phone: (317) 233-1864 or (800) 451-6027, ext. 31864 (within Indiana)
Option # 2
☐ Certification for Termination of Construction Activities:

By Signing this Notice of Termination, I Certify the Following:
A. All land disturbing activities, including construction on all building lots have been completed and the entire site has been stabilized;
B. No future land disturbing activities will occur on this project site;
C. All temporary erosion and sediment control measures have been removed; and
D. A copy of this notice has been sent to the appropriate SWCD or other designated entity.

Option # 3
☐ Notice of Termination to Obtain Early Release from Compliance with 327 IAC 15-5

By Signing this Notice of Termination, I Certify the Following:
A. The remaining, undeveloped acreage does not exceed five (5) acres, with contiguous areas not to exceed one (1) acre.
B. A map of the project site, clearly identifying all remaining undeveloped lots, is attached to this letter. The map must be accompanied by a list of names and addresses of individual lot owners or individual lot operators of all undeveloped lots.
C. All public and common improvements, including infrastructure, have been completed and permanently stabilized and have been transferred to the appropriate local entity.
D. The remaining acreage does not pose a significant threat to the integrity of the infrastructure, adjacent properties, or water quality.
E. All permanent storm water quality measures have been implemented and are operational.

Upon Written Notification of the Department the Project Site Owner Certifies that he/she will Notify:
A. All current individual lot owners and all subsequent individual lot owners of the remaining undeveloped acreage and acreage with construction activity that they are responsible for complying with section 7.5 of 327 IAC 15-5 (the remaining individual lot owners do not need to submit a Notice of Intent letter or Notice of Termination letter); and
B. The individual lot owners of the requirements to install and maintain appropriate measures to prevent sediment from leaving the individual building lot and maintain all erosion and sediment control measures that are to remain on-site as part of the construction plan.

Project Site Owner Responsibility Statement:
By signing this Notice of Termination letter, I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations.

Printed Name of Project Site Owner:
Name:
Signature: ______________________________ Date: __________________

This Notice of Termination must be signed by an individual meeting the signatory requirements in 327 IAC 15-4-3(g).

Please submit the completed Notice of Termination form to the SWCD, DNR-DSC, or other Entity Designated by the Department as the reviewing agency. The request for termination will be reviewed for concurrence and either returned to the Project Site Owner or forwarded to the IDEM.

For Agency Use Only

☐ Accepted: The site referenced above has been inspected and it has been determined that the request to terminate this project is compliant with the requirements of 327 IAC 15-5-8. This form will be forwarded to the IDEM for final approval. Upon written notification by the IDEM, the Project Site Owner's termination for coverage under 327 IAC 15-5 shall be considered approved.

☐ Denied: The site referenced above has been inspected and it has been determined that the request to terminate this project is NOT compliant with the requirements of 327 IAC 15-5-8. Continue to implement the Stormwater Pollution Prevention Plan and take appropriate measures to minimize the discharge of pollutants.

Signature: __________________________ Printed Name: __________________________ Agency: __________________________ Date: __________________________
NOTICE OF TERMINATION INSPECTION
(To be Completed by the City of Greenfield)

All construction sites shall undergo a final inspection by the City of Greenfield following submittal of a Notice of Termination (NOT) by the project owner to ensure the site is stabilized and that post construction BMPs have been properly installed.

B4 – Individual Residential Permit Forms

Instructions Residential Lot Plot Plan Permit Request
Residential Lot Plot Plan Permit Request Application
Individual Lot Typical Erosion & Sediment Control Plan and Certification
INSTRUCTIONS FOR RESIDENTIAL LOT PLOT PLAN
PERMIT REQUEST

1. Request shall be made to the Engineering and Planning Office.
2. Request shall be made on standard form only, supplied by the Engineering and Planning Office.
3. The form shall be completely filled out, including the following information:
   a. Name of subdivision/minor plat and lot number.
   b. Section/Township/Range
   c. Parcel number of property involved.
   d. Project name (if none then put individual’s name).
   e. Contact person(s).
   f. Type of residential lot and/or improvement. This office may require more details depending on the type of improvements being proposed.
4. A certified Plot Plan, including site layout (per Article 6, Section 6.04 of the Stormwater Management Ordinance), is required to be submitted with each permit application.
5. An erosion and sediment control plan is required to be submitted with each Improvement Location Permit application with land disturbance of 10,000 square feet or greater. This plan must conform to the minimum requirements in Article 6, Section 6.04 of the Stormwater Management Ordinance.
6. Applicant will need to provide the name, address telephone number, and list of qualifications of the trained individual in charge of the mandatory stormwater pollution prevention self-monitoring program for the project site.
7. Applicant will need to abide by any additional requirements set forth in Article 6, Section 6.04, of the City of Greenfield Stormwater Management Ordinance.
8. The applicant or an agent of the applicant must sign the form.
9. Check or money order is to be made payable to the City of Greenfield. The correct amount of fee, based on the Fee Ordinance, must be included with the application package.

APPENDIX C

CONSTRUCTION BMPs
DESCRIPTION

The construction sequence schedule is an orderly listing of all major land-disturbing activities together with the necessary erosion and sedimentation control measures planned for the project. This type of schedule guides the contractor on work to be done before other work is started so that serious erosion and sedimentation problems can be avoided. Sequencing a construction project reduces the amount and duration of soil exposed to erosion by wind, rain, runoff, and vehicle tracking.

ADVANTAGE

Following a specified work schedule that coordinates the timing of land-disturbing activities and the installation of control measures is perhaps the most cost-effective way of controlling erosion during construction. The removal of surface ground cover leaves a site vulnerable to accelerated erosion. Construction procedures that limit land clearing, provide timely installation of erosion and sedimentation controls, and restore protective cover quickly can significantly reduce the erosion potential of a site.

DESIGN CRITERIA

1. Avoid rainy periods.
2. Schedule projects to disturb only small portions of the site at any one time. Complete grading as soon as possible. Immediately stabilize the disturbed portion before grading the next portion. Practice staged seeding in order to revegetate cut and fill slopes as the work progresses.

REFERENCE

City of Tacoma, Surface Water Management Manual, 2003 or later
DESCRIPTION

When a stabilized construction entrance is not preventing sediment from being tracked onto the pavement, a wheel wash may be installed. Wheel washing is generally an effective BMP when installed with careful attention to topography. A wheel wash can be detrimental if installed at the top of a slope abutting a right-of-way where the water from the dripping truck can run unimpeded into the street. Pressure washing combined with an adequately sized and surfaced pad with direct drainage to a large 10-foot x 10-foot sump can be very effective.

ADVANTAGES

Wheel washes reduce the amount of sediment transported onto paved roads by motor vehicles.

DESIGN CRITERIA

1. Suggested details are shown in Figure CN-102-A. The City Engineer may allow other designs.
2. A minimum of 6 inches of asphalt treated base (ATB) over crushed base material or 8 inches over a good subgrade is recommended to pave the wheel wash.
3. Use a low clearance truck to test the wheel wash before paving. Either a belly dump or lowboy will work well to test clearance.
4. Keep the water level from 12 to 14 inches deep to avoid damage to truck hubs and filling the truck tongues with water.
5. Midpoint spray nozzles are only needed in extremely muddy conditions.
6. Wheel wash systems should be designed with a small grade change, 6 to 12 inches for a 10-foot-wide pond, to allow sediment to flow to the low side of pond to help prevent re-suspension of sediment.
7. A drainpipe with a 2- to 3-foot riser should be installed on the low side of the pond to allow for easy cleaning and refilling.
8. Polymers may be used to promote coagulation and flocculation in a closed-loop system. Polyacrylamide (PAM) added to the wheel wash water at a rate of 0.25 - 0.5 pounds per 1,000 gallons of water increases effectiveness and reduces cleanup time.
9. If PAM is already being used for dust or erosion control and is being applied by a water truck, the same truck can be used to change the wash water.
10. The wheel wash should start out the day with fresh water. The wash water should be changed a minimum of once per day.
11. On large earthwork jobs where more than 10-20 trucks per hour are expected, the wash water will need to be changed more often.
12. Wheel wash or tire bath wastewater shall be discharged to a separate on-site treatment system, such as closed-loop recirculation or land application, or to the sanitary sewer with proper local sewer utility approval.

REFERENCE

City of Tacoma, Surface Water Management Manual, 2003 or later.
Notes:
1. Asphalt construction entrance 6 in. asphalt treated base (ATB).
2. 3-inch trash pump with floats on the suction hose.
3. Midpoint spray nozzles, if needed.
4. 6-inch sewer pipe with butterfly valves. Bottom one is a drain. Locate top pipe’s invert 1 foot above bottom of wheel wash.
5. 8 foot x 8 foot sump with 5 feet of catch. Build so can be cleaned with backhoe.
6. Asphalt curb on the low road side to direct water back to pond.
7. 6-inch sleeve under road.
8. Ball valves.
9. 15 foot, ATB apron to protect ground from splashing water.

Figure CN-102-A
DESCRIPTION

Water which is pumped from a construction site usually contains a large amount of sediment. A dewatering structure is designed to remove the sediment before water is released off-site.

This practice includes several types of dewatering structures which have different applications dependent upon site conditions and types of operation. Other innovative techniques for accomplishing the same purpose are encouraged, but only after specific plans and details are submitted to and approved by the City Engineer.

DESIGN CRITERIA

1. A dewatering structure must be sized (and operated) to allow pumped water to flow through the filtering device without overtopping the structure.
2. Material from any required excavation shall be stored in an area and protected in a manner that will prevent sediments from eroding and moving off-site.
3. An excavated basin (applicable to “Straw Bale/Silt Fence Pit”) may be lined with filter fabric to help reduce scour and to prevent the inclusion of soil from within the structure.
4. Design criteria more specific to each particular dewatering device can be found in Figures CN-103-A through CN-103-C.
5. A dewatering structure may not be needed if there is a well-stabilized, vegetated area onsite to which water may be discharged. The area must be stabilized so that it can filter sediment and at the same time withstand the velocity of the discharged water without eroding. A minimum filtering length of 75 feet must be available in order for such a method to be feasible.
6. The filtering devices must be inspected frequently and repaired or replaced once the sediment build-up prevents the structure from functioning as designed.
7. The accumulated sediment which is removed from a dewatering device must be spread on-site and stabilized or disposed of at an approved disposal site as per approved plan.

Portable Sediment Tank (see Figure CN103-A)

- The structure may be constructed with steel drums, sturdy wood or other material suitable for handling the pressure exerted by the volume of water.
- Sediment tanks will have a minimum depth of 2 ft.
- The sediment tank shall be located for easy clean-out and disposal of the trapped sediment and to minimize the interference with construction activities.
- The following formula shall be used to determine the storage volume of the sediment tank:
  \[ \text{Pump discharge (gallons/min.)} \times 16 = \text{cubic feet of storage required} \]
- Once the water level nears the top of the tank, the pump must be shut off while the tank drains and additional capacity is made available.
- The tank shall be designed to allow for emergency flow the over top of the tank. Clean-out of the tank is required once one-third of the original capacity is depleted due to sediment accumulation. The tank shall be clearly marked showing the clean-out point.

Filter Box (see Figure CN-103-B)

- The box selected should be made of steel, sturdy wood or other materials suitable to handle the pressure requirements imposed by the volume of water. Normally readily available 55 gallon drums welded top to bottom will suffice in most cases.
- Bottom of the box shall be made porous by drilling holes (or some other method).
Coarse aggregate shall be placed over the holes at a minimum depth of 12 inches, metal “hardware” cloth may need to be placed between the aggregate and the holes if holes are drilled larger than the majority of the stone.

As a result of the fast rate of flow of sediment-laden water through the aggregate, the effluent must be directed over a well-vegetated strip of at least 50 feet after leaving the base of the filter box.

The box shall be sized as follows:

\[
Pump \text{ discharge (gallons/min.)} \times 16 = \text{cubic feet of storage required}
\]

Once the water level nears the top of the box, the pump must be shut off while the box drains and additional capacity is made available.

The box shall be designed/constructed to allow for emergency flow over the top of this box.

Clean-out of the box is required once one-third of the original capacity is depleted due to sediment accumulation. The tank shall be clearly marked showing the clean-out point.

If the stone filter does become clogged with sediment so that it no longer adequately performs its function, the stones must be pulled away from the inlet, cleaned and replaced.

Using a filter box only allows for minimal settling time for sediment particles; therefore, it should only be used when site conditions restrict the use of the other methods.

Straw Bale/Silt Fence Pit (see Figure CN-103-C)

Measure shall consist of straw bales, silt fence, a stone outlet (a combination of riprap and aggregate) and a wet storage pit oriented as shown in Figure CN-103-C.

The structure must have a capacity which is dictated by the following formula:

\[
Pump \text{ discharge (gallons/min.)} \times 16 = \text{cubic feet of storage required}
\]

In calculating the capacity, one should include the volume available from the floor of the excavation to the crest of the stone weir.

In any case, the excavated area should be a minimum of 3 feet below the base of the perimeter measures (straw bales or silt fence).

The perimeter measures must be installed as per the guidelines found in BMP-4, STRAW BALE BARRIER and BMP-5, SILT FENCE.

Once the water level nears the crest of the stone weir (emergency overflow), the pump must be shut off while the structure drains down to the elevation of the wet storage.

The wet storage pit may be dewatered only after a minimum of 6 hours of sediment settling time. This effluent should be pumped across a well vegetated area or through a silt fence prior to entering a watercourse.

Once the wet storage area becomes filled to one-half of the, excavated depth, accumulated sediment shall be removed and properly disposed of.

Once the device has been removed, ground contours will be returned to original condition.

SPILL PREVENTION AND CONTROL

DESCRIPTION

These procedures and practices are implemented to prevent and control spills in a manner that minimizes or prevents the discharge of spilled material to the drainage system or watercourses.

This best management practice (BMP) applies to all construction projects. Spill control procedures are implemented anytime chemicals and/or hazardous substances are stored. Substances may include, but are not limited to:

- Soil stabilizers/binders
- Dust Palliatives
- Herbicides
- Growth inhibitors
- Fertilizers
- Deicing/anti-icing chemicals
- Fuels
- Lubricants
- Other petroleum distillates

To the extent that the work can be accomplished safely, spills of oil, petroleum products, sanitary and septic wastes, and substances listed under 40 Code of Federal Regulations (CFR) parts 110, 117, and 302 shall be contained and cleaned up immediately.

LIMITATIONS

1. This BMP only applies to spills caused by the contractor.
2. Procedures and practices presented in this BMP are general. Contractor shall identify appropriate practices for the specific materials used or stored on-site in advance of their arrival at the site.

DESIGN CRITERIA

1. To the extent that it doesn’t compromise clean up activities, spills shall be covered and protected from stormwater runoff during rainfall.
2. Spills shall not be buried or washed with water.
3. Used clean up materials, contaminated materials, and recovered spill material that is no longer suitable for the intended purpose shall be stored and disposed of in conformance with BMP CN-106: Hazardous Waste Management.
4. Water used for cleaning and decontamination shall not be allowed to enter storm drains or watercourses and shall be collected and disposed of in accordance with BMP CN-106: Hazardous Waste Management.
5. Water overflow or minor water spillage shall be contained and shall not be allowed to discharge into drainage facilities or watercourses. Proper storage, clean-up and spill reporting instruction for hazardous materials stored or used on the project site shall be posted at all times in an open, conspicuous and accessible location.
6. Waste storage areas shall be kept clean, well organized and equipped with ample clean-up supplies as appropriate for the materials being stored. Perimeter controls, containment structures, covers and liners shall be repaired or replaced as needed to maintain proper function.
8. Verify weekly that spill control and clean up materials are located near material storage, unloading, and use areas.

9. Update spill prevention and control plans and stock appropriate clean-up materials whenever changes occur in the types of chemicals used or stored onsite.

and Storage Procedures for Minor Spills
- Minor spills typically involve small quantities of oil, gasoline, paint, etc., which can be controlled by the first responder at the discovery of the spill.
- Use absorbent materials on small spills rather than hosing down or burying the spill.
- Remove the absorbent materials promptly and dispose of properly.
- The practice commonly followed for a minor spill is:
  - Contain the spread of the spill.
  - Recover spilled materials.
  - Clean the contaminated area and/or properly dispose of contaminated materials.

Cleanup and Storage Procedures for Semi-Significant Spills
- Semi-significant spills still can be controlled by the first responder along with the aid of other personnel such as laborers and the foreman, etc. This response may require the cessation of all other activities.
- Clean up spills immediately:
  - Notify the project foreman immediately. The foreman shall notify the City of Greenfield Emergency Management Agency’s Hazardous Materials Response Team.
  - Contain spread of the spill.
  - If the spill occurs on paved or impermeable surfaces, clean up using "dry" methods (absorbent materials, cat litter and/or rags). Contain the spill by encircling with absorbent materials and do not let the spill spread widely.
  - If the spill occurs in dirt areas, immediately contain the spill by constructing an earthen dike. Dig up and properly dispose of contaminated soil.
  - If the spill occurs during rain, cover spill with tarps or other material to prevent contaminating runoff.

Cleanup and Storage Procedures for Significant/Hazardous Spills
- For significant or hazardous spills that cannot be controlled by personnel in the immediate vicinity, notify the local emergency response by dialing 911. In addition to 911, the contractor will notify the proper City officials. It is the contractor's responsibility to have all emergency phone numbers at the construction site.
- For spills of federal reportable quantities, in conformance with the requirements in 40 CFR parts 110, 119, and 302, the contractor shall notify the National Response Center at (800) 424-8802.
- Notification shall first be made by telephone and followed up with a written report.
- The services of a spills contractor or a Haz-Mat team shall be obtained immediately. Construction personnel shall not attempt to clean up the spill until the appropriate and qualified personnel have arrived at the job site.

REFERENCE

California Department of Transportation, Construction Site BMP Manual, 2000 or later.
DESCRIPTION

Solid waste management procedures and practices are designed to minimize or eliminate the discharge of pollutants to the drainage system or to watercourses as a result of the creation, stockpiling, or removal of construction site wastes.

Solid waste management procedures and practices are implemented on all construction projects that generate solid wastes.

Solid wastes include but are not limited to:

1. Construction wastes including brick, mortar, timber, steel and metal scraps, sawdust, pipe and electrical cuttings, non-hazardous equipment parts, styrofoam and other materials used to transport and package construction materials.
2. Landscaping wastes, including vegetative material, plant containers, and packaging materials.
3. Litter, including food containers, beverage cans, coffee cups, paper bags, plastic wrappers, and smoking materials, including litter generated by the public.

LIMITATIONS

Temporary stockpiling of certain construction wastes may not necessitate stringent drainage related controls during the non-rainy season.

DESIGN CRITERIA

1. Dumpsters of sufficient size and number shall be provided to contain the solid waste generated by the project and properly serviced.
2. Littering on the project site shall be prohibited.
3. To prevent clogging of the storm drainage system, litter and debris removal from drainage grates, trash racks, and ditch lines shall be a priority.
4. Trash receptacles with lids shall be provided in the contractor’s yard, field trailer areas, and at locations where workers congregate for lunch and break periods.
5. Construction debris and litter from work areas within the construction limits of the project site shall be collected and placed in watertight dumpsters at least weekly regardless of whether the litter was generated by the contractor, the public, or others. Collected litter and debris shall not be placed in or next to drain inlets, storm water drainage systems or watercourses.
6. Full dumpsters shall be removed from the project site and the contents shall be disposed of, off-site, in an appropriate manner.
7. Litter stored in collection areas and containers shall be handled and disposed of by trash hauling contractors.
8. Construction debris and waste shall be removed from the site every two weeks.
9. Stormwater run-off shall be prevented from contacting stored solid waste through the use of berms, dikes, or other temporary diversion structures or through the use of measures to elevate waste from site surfaces.
10. Solid waste storage areas shall be located at least 50 ft from drainage facilities and watercourses and shall not be located in areas prone to flooding or ponding. Except during fair weather, construction and landscaping waste not stored in watertight dumpsters shall be securely covered from wind and rain by covering the waste with tarps, plastic sheeting, or equivalent.
11. Dumpster washout on the project site is not allowed.
12. Notify trash hauling contractors that only watertight dumpsters are acceptable for use on-site.
13. Plan for additional containers during the demolition phase of construction.
14. Plan for more frequent pickup during the demolition phase of construction.
15. Construction waste shall be stored in a designated area. Access to the designated area shall either be well vegetated ground, a concrete or asphalt road or drive, or a gravel construction entrance, to avoid mud tracking by trash hauling contractors.
16. Segregate potentially hazardous waste from non-hazardous construction site waste.
17. Keep the site clean of litter debris.
18. Make sure that toxic liquid wastes (e.g., used oils, solvents, and paints) and chemicals (e.g., acids, pesticides, additives, curing compounds) are not disposed of in dumpsters designated for construction debris.
19. For disposal of hazardous waste, see BMP CN-106: Hazardous Waste Management. Have hazardous waste hauled to an appropriate disposal and/or recycling facility.
20. Salvage or recycle useful vegetation debris, packaging and/or surplus building materials when practical. For example, trees and shrubs from land clearing can be converted into wood chips, then used as mulch on graded areas. Wood pallets, cardboard boxes, and construction scraps can also be recycled.
21. Prohibit littering by employees, subcontractors, and visitors.
22. Wherever possible, minimize production of solid waste materials.

Appendix D
Post-Construction BMPs
DESCRIPTION

Bioretention is a best management practice (BMP) developed in the early 1990's by the Prince George’s County, MD, Department of Environmental Resources (PGDER). Bioretention utilizes soils and both woody and herbaceous plants to remove pollutants from stormwater runoff. As shown in Figure PC-101A, runoff is conveyed as sheet flow to the treatment area, which consists of a grass buffer strip, sand bed, ponding area, organic layer or mulch layer, planting soil, and plants. Runoff passes first over or through a sand bed, which slows the runoff’s velocity, distributes it evenly along the length of the ponding area, which consists of a surface organic layer and/or ground cover and the underlying planting soil. The ponding area is graded; its center depressed. Water is ponded to a depth of 6 inches and gradually infiltrates the bioretention area and/or is evaporated. Bioretention areas are applicable as on-lot retention facilities that are designed to mimic forested systems that naturally control hydrology. The bioretention area is graded to drain excess runoff over a weir and into the storm drain system. Stored water in the bioretention area planting soil infiltrates over a period of days into the underlying soils.

The basic bioretention design shown below can be modified to accommodate more specific needs. The bioretention BMP design can be modified to include an underdrain within the sand bed to collect the infiltrated water and discharge it to a downstream storm drain system. This modification may be required when impervious subsoils and marine clays prevent complete infiltration in the soil system. This modified design makes the bioretention area act more as a filter that discharges treated water than as an infiltration device.

COMPONENTS

1. Grass Buffer Strip -Designed to filter out particulates and reduce runoff velocity.
2. Sand Bed -Further reduces velocity by capturing a portion of the runoff and distributes it evenly along the length of the ponding area. Also provides aeration to the plant bed and enhances infiltration.
3. Ponding Area -Collects and stores runoff prior to infiltration.
4. Organic/Mulch Layer -Provides some filtering of runoff, encourages development of beneficial microorganisms, and protects the soil surface from erosion.
5. Planting Soil -Provides nourishment for the plant life. Clay particles within the soil also remove certain pollutants through adsorption.
6. Plants -Provides uptake of harmful pollutants.

ADVANTAGES

1. If designed properly, has shown ability to remove significant amounts of dissolved heavy metals, phosphorous, TSS, and fine sediments.
2. Requires relatively little engineering design in comparison to other stormwater management facilities (e.g. sand filters).
3. Provides groundwater recharge when the runoff is allowed to infiltrate into the subsurface.
4. Enhances the appearance of parking lots and provides shade and wind breaks, absorbs noise, and improves an area’s landscape.
5. Maintenance on a bioretention facility is limited to the removal of leaves from the bioretention area each fall.
6. The vegetation recommended for use in bioretention facilities is generally hardier than the species
typically used in parking lot landscapes. This is a particular advantage in urban areas where plants often fare poorly due to poor soils and air pollution.

LIMITATIONS

1. Low removal of nitrates.
2. Not applicable on steep, unstable slopes or landslide areas (slopes greater than 20 percent).
3. Requires relatively large areas.
4. Not appropriate at locations where the water table is within 6 feet of the ground surface and where the surrounding soil stratum is unstable.
5. Clogging may be a problem, particularly if the BMP receives runoff with high sediment loads.

DESIGN CRITERIA

1. Calculate the volume of stormwater to be mitigated by the bioretention facility using the water quality volume calculations outlined in Chapter 9.
2. The soil should have infiltration rates greater than 0.5 inches per hour, otherwise an underdrain system should be included (see # 11).
3. Drainage to the bioretention facility must be graded to create sheet flow, not a concentrated stream. Level spreaders (i.e. slotted curbs) can be used to facilitate sheet flow. The maximum sheet flow velocity should be 1 ft/s for the planted ground cover and 3 ft/s for mulched cover.
4. Soil shall be a uniform mix, free of stones, stumps, roots or other similar objects larger than 1-inch in diameter. No other materials or substances shall be mixed or dumped within the bioretention area that may be harmful to plant growth, or prove a hindrance to the planting or maintenance operations. The planting soil shall be free of noxious weeds.
5. Planting soil shall be tested and meet the following criteria:

<table>
<thead>

6. It is very important to minimize compaction of both the base of the bioretention area and the required backfill. When possible, use excavation hoes to remove original soil. If excavated using a loader, the excavator should use a wide track or marsh track equipment, or light equipment with turf type tires. Use of equipment with narrow tracks or narrow tires, rubber tires with large lugs, or high pressure tires will cause excessive compaction resulting in reduced infiltration rates and storage volumes and is not acceptable. Compaction will significantly contribute to design failure.

7. Compaction can be alleviated at the base of the bioretention facility by using a primary tilling operation such as a chisel plow, ripper, or subsoiler. These tilling operations are to refracture the soil profile through the 12 inch compaction zone. Substitute methods must be approved by the engineer. Rototillers typically do not till deep enough to reduce the effects of compaction from heavy equipment. Rototill 2 to 3 inches of sand into the base of the bioretention facility before back filing.
the required sand layer. Pump any ponded water before preparing (rototilling) base.

8. When back filling topsoil over the sand layer, first place 3 to 4 inches of topsoil over the sand, then rototill the sand/topsoil to create a gradation zone. Backfill the remainder of the topsoil to final grade.

9. Mulch around individual plants only. Shredded hardwood mulch is the only accepted mulch. Shredded hardwood mulch must be well aged (stockpiled or stored for at least 12 months) for acceptance. The mulch should be applied to a maximum depth of 3-inches.

10. The plant root ball should be planted so \( \frac{1}{8} \) of the ball is above final grade surface.

11. If used, place underdrains on a 3 feet wide section of filter cloth followed by a gravel bedding. Pipe is placed next, followed by the gravel bedding. The ends of underdrain pipes not terminating in an observation well shall be capped.

12. The main collector pipe for underdrain systems shall be constructed at a minimum slope of 0.5%. Observation wells and/or clean-out pipes must be provided (one minimum per every 1,000 square feet of surface area).

13. Size an emergency overflow weir with 6-inches of head, using the Weir equation: \( Q=CLH^{3/2} \)  Where 

\[
C= 2.65 \quad \text{(smooth crested grass weir)}
\]

14. Bioretention areas should be at least 15 feet wide with a 25 foot width preferable, and a minimum length of 40 feet long. Generally, the length-to-width ratio should be around 2 to 1 to improve surface flow characteristics.

15. The plant soil depth should be 4 feet or more to provide beneficial root zone, both in terms of space and moisture content.

16. The depth of the ponding area should be limited to no more than 6 inches to limit the duration of standing water to no more than 4 days. If an underdrain system is used, the depth of the ponding area should be limited to no more than 1 foot. Longer ponding times can lead to anaerobic conditions that are not conducive to plant growth. Longer periods of standing water can also lead to the breeding of mosquitoes and other pests.

17. The bioretention area should be vegetated to resemble a terrestrial forest community ecosystem, which is dominated by understory trees, a shrub layer, and herbaceous ground covers. Three species each of both trees and shrubs are recommended to be planted at a rate of 1000 total trees and shrubs per acre. The shrub-to-tree ratio should be 2:1 to 3:1. Trees should be spaced 12 feet apart and the shrubs should be spaced 8 feet apart.

Schematic of Bioretention Area (SUSMP, 2002)
DESCRIPTION

Wetlands provide physical, chemical, and biological water quality treatment of stormwater runoff. Physical treatment occurs as a result of decreasing flow velocities in the wetland, and is present in the form of evaporation, sedimentation, adsorption, and/or filtration. Chemical processes include chelation, precipitation, and chemical adsorption. Biological processes include decomposition, plant uptake and removal of nutrients, plus biological transformation and degradation. Hydrology is one of the most influential factors in pollutant removal due to its effects on sedimentation, aeration, biological transformation, and adsorption onto bottom sediments (Dormann, et al., 1988). The large surface area of the bottom of the wetland encourages higher levels of adsorption, absorption, filtration, microbial transformation, and biological utilization than might normally occur in more channelized water courses.

A natural wetland is defined by examination of the soils, hydrology, and vegetation which are dominant in the area. Wetlands are characterized by the substrate being predominantly undrained hydric soil. A wetland may also be characterized by a substrate which is non-soil and is saturated with water or covered by shallow water at some time during the growing season of each year. Wetlands also usually support hydrophytes, or plants which are adapted to aquatic and semiaquatic environments. Natural and artificial wetlands are used to treat stormwater runoff. Figure PC-102A illustrates an artificial wetland used for treating stormwater runoff.

The success of a wetland will be much more likely if some general guidelines are followed. The wetland should be designed such that a minimum amount of maintenance is required. This will be affected by the plants, animals, microbes, and hydrology. The natural surroundings, including such things as the potential energy of a stream or a flooding river, should be utilized as much as possible. It is necessary to recognize that a fully functional wetland cannot be established spontaneously. Time is required for vegetation to establish and for nutrient retention and wildlife enhancement to function efficiently. Also, the wetland should approximate a natural situation as much as possible, and unnatural attributes, such as a rectangular shape or a rigid channel, should be avoided (Mitsch and Gosselink, 1993).

1. Natural Wetland Systems. Existing wetlands perform storm water treatment in the same fashion as constructed wetlands. However, current policy of the Indiana Department of Environmental Management prohibit the use of existing wetlands as a pollution control measure. Therefore, the use of existing wetlands as a proposed BMP cannot be accepted under any circumstance by the City Engineer without the prior written acceptance by IDEM for such proposed pollution control use.

2. Constructed (Artificial) Wetlands. Site considerations should include the water table depth, soil/substrate, and space requirements. Because the wetland must have a source of flow, it is desirable that the water table is at or near the surface. This is not always possible. If runoff is the only source of inflow for the wetland, the water level often fluctuates and establishment of vegetation may be difficult. The soil or substrate of an artificial wetland should be loose loam to clay. A perennial base flow must be present to sustain the artificial wetland. The presence of organic material is often helpful in increasing pollutant removal and retention.
Wetland vegetation can be categorized as emergent, floating, or submerged. Emergent vegetation is rooted in the sediments, but grows through the water and above the water surface. Floating vegetation is not rooted in the sediments, and has aquatic roots with plant parts partly submerged or fully exposed on the water or surface. Submerged vegetation includes aquatic plants such as algae or plants rooted in the sediments, with all plant parts growing within the water column. Pollutant removal rates generally improve with an increase in the diversity of the vegetation.

The depth of inundation will contribute to the pollutant removal efficiency. Generally, shallow water depths allow for higher pollutant removal efficiencies due to an increased amount of adsorption onto bottom sediments (Dormann, et al., 1988). Flow patterns in the wetland will affect the removal efficiency also. Meandering channels, slow-moving water and a large surface area will increase pollutant removal through increased sedimentation. Shallow, sheet flow also increases the pollutant removal capabilities, through assimilative processes. A deep pool sometimes improves the denitrification potential. A mixed flow pattern will increase overall pollutant removal efficiency (Dormann, et al., 1988).

Using a site where nearby wetlands still exist is recommended if possible. A hydrologic study should be done to determine if flooding occurs and saturated soils are present. A site where natural inundation is frequent is a good potential site (Mitsch and Gosselink, 1993). Loamy soils are required to permit plants to take root (Urbonas, 1992).

**ADVANTAGES**

1. Constructed wetlands offer natural aesthetic qualities, wildlife habitat, erosion control, and pollutant removal.
2. Constructed wetlands can offer good treatment following treatment by other BMPs, such as wet ponds, that rely upon settling of larger sediment particles (Urbonas, 1992). They are useful for large basins when used in conjunction with other BMPs.
3. Wetlands which are permanently flooded are less sensitive to polluted water inflows because the ecosystem does not depend upon the polluted water inflow.
4. Can provide uptake of soluble pollutants such as phosphorous, through plant uptake.
5. Can be used as a regional facility.

**LIMITATIONS**

1. Although the use of natural wetlands may be appear to be more cost effective than the use of constructed wetlands; environmental, permitting and legal issues prohibit the use of natural wetlands for this purpose.
2. Wetlands require a continuous base flow.
3. If not properly maintained, wetlands can accumulate salts and scum which can be flushed out by large storm flows.
4. Regular maintenance, including plant harvesting, is required to provide nutrient removal.
5. Frequent sediment removal is required to maintain the proper functioning of the wetland.
6. A greater amount of space is required for a wetland system than is required for an extended/dry detention basin treating the same amount of area.
7. Although constructed wetlands are designed to act as nutrient sinks, on occasion, the wetland may periodically become a nutrient source.
8. Wetlands which are not permanently flooded are more likely to be affected by drastic changes in inflow of polluted water.
9. Cannot be used on steep unstable slopes or densely populated areas.
10. Harvested wetlands may require special disposal methods, due to heavy metal uptake.
11. Threat of mosquitoes.
12. Hydraulic capacity may be reduced with plant overgrowth.

DESIGN CRITERIA

The wetland may be designed as either a stand-alone BMP, or as part of a larger non-point source treatment facility in conjunction with other devices, such as a wet pond, sediment forebay, or infiltration basin. Basic design elements and considerations are listed below.

1. Volume. The wetland pond should provide a minimum permanent storage equal to three-fourths of the water quality volume. The full water quality capture volume should be provided above the permanent pool. Calculate the water quality volume to be mitigated by the wetland using the method of Chapter 9.

2. Depth. A constant shallow depth should be maintained in the wetland, at approximately 1 ft or less (Schueler, 1987; Boutiette and Duerring, 1994), with 0.5 ft being more desirable (Schueler, 1987). If the wetland is designed as a very shallow detention pond, the pond should provide the full water quality capture volume above the permanent pool level. The permanent wetland depth should be 6 to 12 inches deep. The depth of the water quality volume above the permanent pool should not exceed 2 ft (Urbonas, 1992). Regrading may be necessary to allow for this shallow depth over a large area.

It may also be beneficial to create a wetland with a varying depth. A varying depth within the wetland will enable more diverse vegetation to flourish. Deep water offers a habitat for fish, creates a low velocity area where flow can be redistributed, and can enhance nitrification as a prelude to later denitrification if nitrogen removal is desired. Open-water areas may vary in depth between 2 and 4 ft (Urbonas, 1992).

3. Surface Area. Increasing the surface area of the pond increases the nutrient removal capability (Boutiette and Duerring, 1994). A general guideline for surface area is using a marsh area of two to three percent of the contributing drainage area. The minimum surface area of the pond can also be calculated by determining the nutrient loading to the wetland. The nutrient loading to a wetland used for stormwater treatment should not be more than 45 lbs/ac of phosphorus or 225 lbs/ac of nitrogen per year. The pond could be sized to meet this minimum size requirement if the annual nutrient load at the site is known (Schueler, 1987). If unknown, the nutrient loads can be estimated using the methodology of Chapter 8.

5. Base flow. Enough inflow must be present in the wetland to maintain wetland soil and vegetation conditions. A water balance should be calculated. Dependence on groundwater for a moisture supply is not recommended.

\[ S = Qi + R + Inf - Qo - ET \]

Where:
- \( S \) = net change in storage
- \( Qi \) = stormwater runoff inflow
- \( R \) = contribution from rainfall
- \( Inf \) = net infiltration (infiltration – exfiltration)
- \( Qo \) = surface outflow
ET = evapotranspiration

6. **Seeding.** It is important that any seed which is used to establish vegetation germinate and take root before the site is inundated, or the seeds will be washed away. Live plants (plugs) should be considered for areas inundated even during construction.

7. **Length to Width Ratio.** The pond should gradually expand from the inlet and gradually contract toward the outlet. The length to width ratio of the wetland should be 2:1 to 4:1, with a length to width ratio of 3:1 recommended (Urbonas, 1992).

8. **Emptying Time.** The water quality volume above the permanent pool should empty in approximately 24 hours (Urbonas, 1992). This emptying time is not for the wetland itself, but for the additional storage above the wetland. Failure to approach this criteria is often the source of failure for constructed wetlands planned for the base of a water quantity storage facility.

9. **Inlet and Outlet Protection.** Inlet and outlet protection should be provided to reduce erosion of the basin. Velocity should be reduced at the entrance to reduce resuspension of sediment by using a forebay. The forebay should be approximately 5 to 10 percent of the water quality capture volume. The outlet should be placed in an offbay at least 3 ft deep. It may be necessary to protect the outlet with a skimmer shield that starts approximately one-half of the depth below the permanent water surface and extends above the maximum capture volume depth. A skimmer can be constructed from a stiff steel screen material that has smaller openings than the outlet orifice or perforations.

10. **Infiltration Avoidance.** Loss of water through infiltration should be avoided. This can be done by compacting the soil, incorporating clay into the soil, or lining the pond with artificial lining.

11. **Side Slopes.** Side slopes should be gradual to reduce erosion and enable easy maintenance. Side slopes should not be steeper than 4:1, and 5:1 is preferable (Urbonas, 1992).

12. **Open Water.** At least 25 percent of the basin should be an open water area at least 2 ft deep if the device is exclusively designed as a shallow marsh. The open water area will make the marsh area more aesthetically pleasing, and the combined water/wetland area will create a good habitat for waterfowl (Schueler, 1987). The combination of forebay, outlet and free water surface should be 30 to 50 percent, and this area should be between 2 and 4 ft deep. The wetland zone should be 50 to 70 percent of the area, and should be 6 to 12 inches deep (Urbonas, 1992).

13. **Freeboard.** The wetland pond should be designed with at least 1 ft of freeboard (Camp, Dresser and McKee, 1993).

14. **Use with Wet Pond.** Shallow marshes can be established at the perimeter of a wet pond by grading to form a 10 to 20 ft wide shallow bench. Aquatic emergent vegetation can be established in this area. A shallow marsh area can also be used near the inflow channel for sediment deposition (Schueler, 1987).

15. **Shape.** The shape is an important aspect of the wetland. It is recommended that a littoral shelf with gently sloping sides of 6:1 or milder to a point 24 to 28 inches below the water surface (Mitsch and Gosselink, 1993). Bottom slopes of less than one percent slope are also recommended.

16. **Soils.** Clay soils underlying the wetland will help prevent percolation of water to groundwater. However, clay soils will also prevent root penetration, inhibiting growth. Loam and sandy soils may then be preferable. A good design may be use of local soils at the upper layer with clay beneath to prevent infiltration (Mitsch and Gosselink, 1993).

17. **Vegetation.** Vegetation must be established in the wetland to aid in slowing down velocities, and nutrient uptake in the wetland. A dependable way of establishing vegetation in the wetland is to transplant live plants or dormant rhizomes from a nursery. Emergent plants may eventually migrate into the wetland from upstream, but this is not a reliable source of vegetation. Transplanting vegetation from existing wetland areas is not encouraged, as it may damage the existing wetland area. Seeding is more cost effective, but is also not reliable. Vegetation should be selected by a qualified wetland scientist.

18. **Forebay.** A forebay may be provided to partially protect proposed wetland plantings from sediment loadings. If a forebay is provided, the forebay volume should be about 5 to 10 percent of the water.
quality volume.

Figure PC-102A
Typical Constructed Wetland Components (SUSMP, 2002)
DESCRIPTION

Extended dry detention basins are depressed basins that temporarily store a portion of stormwater runoff following a storm event. Underground detention tanks function similar to detention basins. However, since underground detention tanks are located below ground, the surface above these systems can be utilized for other more useful needs (parking lots, sidewalks, landscaping adjacent to buildings, etc). Water is controlled by means of a hydraulic control structure (orifice and/or weirs) to restrict outlet discharge. The extended dry detention basins and underground detention tanks normally do not have a permanent water pool between storm events. The objectives of both systems are to remove particulate pollutants and to reduce maximum runoff values associated with development to their pre-development levels. Detention basin facilities may be berm-encased areas or excavated basins. Detention tank facilities may be corrugated metal pipe, concrete pipe, or vaults. Figures PC-103A and PC-103B show typical components of Extended Dry Detention and Underground Detention Tanks.

ADVANTAGES

1. Modest removal efficiencies for the larger particulate fraction of pollutants.
2. Removal of sediment and buoyant materials. Nutrients, heavy metals, toxic materials, and oxygen-demanding particles are also removed with sediment substances associated with the particles.
3. Can be designed for combined flood control and stormwater quality control.
4. May require less capital cost and land area when compared to wet pond BMP.
5. Downstream channel protection when properly designed and maintained.

LIMITATIONS

1. Require sufficient area and hydraulic head to function properly.
2. Generally not effective in removing dissolved and finer particulate size pollutants from stormwater.
3. Some constraints other than the existing topography include, but are not limited to, the location of existing and proposed utilities, depth to bedrock, location and number of existing trees, and wetlands.
4. Extended dry detention basins have moderate to high maintenance requirements.
5. Sediments can be resuspended if allowed to accumulate over time and escape through the hydraulic control to downstream channels and streams.
6. Some environmental concerns with using extended dry detention basins, include potential impact on wetlands, wildlife habitat, aquatic biota, and downstream water quality.
7. May create mosquito breeding conditions and other nuisances.

### INFILTRATION BASINS

#### DESCRIPTION

An infiltration basin is a surface pond which captures first-flush stormwater and treats it by allowing it to percolate into the ground and through permeable soils. As the stormwater percolates into the ground, physical, chemical, and biological processes occur which remove both sediments and soluble pollutants. Pollutants are trapped in the upper layers of the soil, and the water is then released to groundwater. Infiltration basins are generally used for drainage areas between 5 and 50 acres (Boutiette and Duerring, 1994). An infiltration trench or other BMPs may be more appropriate for drainage areas less than five (5) acres. Maintenance of an infiltration basin could be burdensome for drainage areas greater than 50 acres. An extended/dry detention basin or wet pond may be more appropriate for these larger areas. Infiltration basins are generally dry except immediately following storms, but a low-flow channel may be necessary if a constant base flow is present.

Infiltration basins create visible surface ponds that dissipate because water is infiltrated through the pond bottom, while infiltration trenches hide surface drainage in underground void regions and the water is infiltrated below the rocks. Infiltration basins effectively remove soluble pollutants because processes such as adsorption and biological processes remove these soluble pollutants from stormwater. This kind of treatment is not always available in other kinds of BMPs.

Several types of infiltration basins exist. They can be either in-line or off-line, and may treat different volumes of water, such as the water quality volume or the 2-year or 10-year storm. A full infiltration basin is built to hold the entire water quality volume, and the only outlet from the pond is an emergency spillway. More commonly used is the combined infiltration/detention basin, where the outflow is controlled by a vertical riser. Excess flow volume spills over the drop inlet at the top of the riser, and very large storms will exit through the emergency spillway. Other types of basins include the side-by-side basin, and the off-line infiltration basin. The side-by-side basin consists of a basin with an elevated channel to carry base flows running along one of its sides. Storm flows also flow through the elevated channel, but overflow the channel and enter the basin when they become deep enough. An off-line infiltration basin is used to treat the first flush runoff, while higher flows remain in the main channel.

#### ADVANTAGES

2. Groundwater recharge helps to maintain dry-weather flows in streams.
3. Can minimize increases in runoff volume.
4. When properly designed and maintained, it can replicate pre-development hydrology more closely than other BMP options.
5. Basins provide more habitat value than other infiltration systems.

#### LIMITATIONS

1. High failure rate due to clogging and high maintenance burden.
2. Low removal of dissolved pollutants in very coarse soils.
3. Not suitable on fill slopes or steep slopes.
4. Risk of groundwater contamination in very coarse soils, may require groundwater monitoring.
5. Should not be used if significant upstream sediment load exists.
6. Slope of contributing watershed needs to be less than 20 percent.
7. Not recommended for discharge to a sole source aquifer.
8. Cannot be located within 100 feet of drinking water wells.
9. Metal and petroleum hydrocarbons could accumulate in soils to potentially toxic levels.
10. Relatively large land requirement.
11. Only feasible where soil is permeable and there is sufficient depth to bedrock and water table.
12. Need to be located a minimum of 10 feet down gradient and 100 feet up gradient from building foundations because of seepage problems.
13. Infiltration facilities could fall under additional regulations of IDEM or IDNR regarding waste disposal to groundwater.

**DESIGN CRITERIA**

Designing an infiltration basin is a process in which several factors are examined. The soil type and the drainage area are important factors in infiltration basin design. If either one of these two is inappropriate, the infiltration basin will not function properly. The steps in the design of an infiltration basin are listed below.

1. **Drainage Area.** Drainage areas between 5 and 50 acres are good candidates for infiltration basins. Infiltration trenches might be more appropriate for smaller drainage areas, while retention ponds are more appropriate for larger drainage areas (Schueler, 1987).
2. **Soils.** The site must have the appropriate soil, or the basin will not function properly. It is important that the soil be able to accept water at a minimum infiltration rate. Soils with an infiltration rate of less than 0.3 inches per hour, are not suitable sites for infiltration basins. Soils with a high percentage of clay are also undesirable, and should not be used if the percentage of clay is greater than 30. Generally, areas with fine to moderately fine soils are prevalent should not be considered as sites, because these soils do not have a high infiltration rate. Soils with greater than 40 percent combined silt/clay also should not be used. A series of soil cores should be taken to a depth of at least 5 feet below the proposed basin floor elevation to determine which kinds of soils are prevalent at the potential site.
3. **Volume.** Calculate the volume of stormwater to be mitigated by the infiltration basin using the methods in Chapter 9.
4. **Slope.** The basin floor should be as flat as possible to ensure an even infiltration surface and should not be or greater than 5 percent slope. Also, side slopes should have a maximum slope of 3 horizontal to 1 vertical (Schueler, 1987).
5. **Vegetation.** Vegetation should be established as soon as possible. Water-tolerant reed canary grass or tall fescue should be planted on the floor and side slopes of the basin (Schueler, 1987). Root penetration and thatch formation maintains and sometimes improves infiltration capacity of the basin floor. Also, the vegetation helps to trap the pollutants by growing through the accumulated sediment and preventing resuspension. The vegetation also helps reduce pollution levels by taking up soluble nutrients for growth and converting them into less available pollutant forms.
6. **Inlet.** Sediment forebays or riprap aprons should be installed to reduce flow velocities and trap sediments upon entrance to the basin. Flow should be evenly distributed over the basin floor by a riprap apron. The inlet pile or channel should enter the basin at floor level to prevent erosion (Schueler, 1987).
7. **Drainage Time.** The basin should completely drain within 24 hours to avoid the risk of it not being empty before the next storm. Overestimation of the future infiltration capacity can result in a standing water problem. Ponds with detention times of less than six hours are not effectively removing pollutants from the storm flows (Schueler, 1987). The most common problem is setting the elevation and size of the low-flow orifice. If the orifice is too large, runoff events pass through the basin too quickly. If the low-flow orifice diameter is too narrow, there is a risk of creating an
undesirable quasi-permanent pool.

8. **Buffer Zone.** A 25 foot buffer should be placed between the edge of the basin floor, and the nearest adjacent lot (Schueler, 1987). The buffer should consist of water tolerant, native plant species that provide food and cover for wildlife. This buffer zone may also act as a screen if necessary.

9. **Access.** Access to the basin floor should be provided for light equipment (Schueler, 1987).

10. **Water Table.** The basin floor should be a minimum of 10 feet above the water table.

11. **Maximum Depth.** The maximum allowable depth is equal to the infiltration rate multiplied by the maximum allowable dewatering time (24 hours).

12. **Freeboard.** A minimum of 2 feet of freeboard should be available between the spillway crest and the top of the dam (Dormann, et al., 1988).

13. **Emergency Spillway.** The emergency spillway should be able to safely pass the 100-year flood.

14. **Surface Area of the Basin Floor.** If the surface area of the basin floor is increased, the infiltration rate and quantity of runoff which can be infiltrated will be increased. Larger surface areas can also help compensate for clogging on the surface.

**REFERENCES**

DESCRIPTION

An infiltration trench is basically an excavated trench that has been lined with filter fabric and backfilled with stone to form an underground basin. Runoff is diverted into the trench and either infiltrates into the soil, or enters a perforated pipe underdrain and is routed to an outflow facility. The depths of an infiltration trench generally range between 3 and 8 feet (Schueler, 1987) and may change when site-specific factors are considered. Smaller trenches are used for water quality, while larger trenches can be constructed if stormwater quantity control is required (Schueler, 1987). Trenches are not usually feasible in ultra-urban or retrofit situations where the soils have low permeability or low voids (Schueler, 1992). They should be installed only after the contributing area has stabilized to minimize runoff of sediments.

Infiltration trenches and infiltration basins follow similar design logic. The differences are that the former is for small drainage areas and stores runoff out of sight, within a gravel or aggregate matrix, whereas the latter is for larger drainage areas and water is stored in a visible surface pond.

Infiltration trenches effectively remove soluble and particulate pollutants. They can provide groundwater recharge by diverting 60 to 90 percent of annual urban runoff back into the soil (Boutiette and Duerring, 1994). They are generally used for drainage areas less than 10 acres, but some references cite 5 acres as a maximum size drainage area (Schueler, 1987, 1992). Potential locations include residential lots, commercial areas, parking lots, and adjacent to road shoulders. Trenches are only feasible on permeable soils (sand and gravel), and where the water table and bedrock are situated well below the bottom of the trench (Boutiette and Duerring, 1994; Schueler, 1987). Trenches are frequently used in combination with grassed swales. Trenches should not be used to trap course sediments, because the large sediment will clog the trench. Grass buffers can be installed to capture sediment before it enters the trench.

ADVANTAGES

1. Provides groundwater recharge.
2. Trenches fit into small areas.
3. Good pollutant removal capabilities.
5. Can fit into medians, perimeters, and other unused areas of a development site.
6. Helps replicate pre-development hydrology and increases dry weather base flow.

LIMITATIONS

1. Slope of contributing watershed needs to be less than 20 percent.
2. Soil should have infiltration rate greater than 0.3 inches per hour and clay content less than 30 percent.
3. Drainage area should be between 1 to 10 acres.
4. The bottom of infiltration trench should be at least 4 feet above the underlying bedrock and the seasonal high water table.
5. High failure rates of conventional trenches and high maintenance burden.
7. Not suitable on fill slopes or steep slopes.
8. Risk of groundwater contamination in very coarse soils, may require groundwater monitoring.
9. Infiltration facilities could fall under additional regulations of IDEM or IDNR regarding waste disposal to groundwater.
10. Cannot be located within 100 feet of drinking water wells.
11. Need to be located a minimum of 10 feet down gradient and 100 feet up gradient from building foundations because of seepage problems.
12. Should not be used if upstream sediment load cannot be controlled prior to entry into the trench.
13. Metals and petroleum hydrocarbons could accumulate in soils to potentially toxic levels.

**DESIGN CRITERIA**

Infiltration trenches can be categorized both by trench type, and as surface or below ground. Special inlets are required for underground trenches to prevent sediment and oil or grease from clogging the infiltration trench (Schueler, 1987). Surface trenches are commonly used where land is not limiting and underground trenches are better suited for development with minimal land availabilities.

1. **Volume.** Calculate the volume of stormwater to be mitigated by the water quality volume calculation in Chapter 9.
2. **Dimensions.** Generally, soils with low infiltration rates require a higher ratio of bottom surface area to storage volume (Northern Virginia Planning District Commission and Engineers and Surveyors Institute, 1992). The following formulas can be used to determine the dimensions of the infiltration basin:

   \[ H_{\text{max}} = E \cdot t_{\text{max}} / P \]
   \[ H_{\text{min}} = E \cdot t_{\text{min}} / P \]
   \[ A = V / \left( E \cdot t_{\text{max}} \right) \]

   Where:
   
   \( H_{\text{max}}, H_{\text{min}} \) = Maximum and minimum trench depths (ft)
   
   \( E \) = Infiltration rate in length per unit time (ft/hr).
   
   \( t_{\text{max}}, t_{\text{min}} \) = Maximum and minimum target drain-time (hr)
   
   \( P \) = Pore volume ratio of stone aggregate (% porosity/100).
   
   \( V \) = Fluid storage volume requirement (ft³)
   
   \( A \) = Trench bottom surface area (ft²).

   The actual storage volume of the facility is the void ratio multiplied by the total volume of the trench. The available land and other constraints such as depth to bedrock or water table are used to determine the final dimensions of the trench.

3. **Buffer Strip/Special Inlet.** A grass filter strip a minimum of 20 feet should surround the trench on all sides over which surface flow reaches an above-ground trench. A special inlet can be used to prevent floatable material, solids, grease, and oil from entering trenches which are located below ground.

4. **Filter Fabric.** The bottom and sides of the trench should be lined with filter fabric soon after the
trench is excavated. The fabric should be flush with the sides, overlap on the order of 2 feet over the seams, and not have trapped air pockets. As an alternative, 6 inches of clean, washed sand may be placed on the bottom of the trench instead of filter fabric.

5. **Grass Cover.** If the trench is grass covered, at least 1 foot of soil should be over the trench for grass substrate.

6. **Surface Area.** The surface area of the trench can be engineered to the site with the understanding that a larger surface area of the bottom of the trench increases infiltration rates and helps to reduce clogging and that depth may be limited by seasonal groundwater.

7. **Surface Area of the Trench Bottom.** Pollutant removal in a trench can be improved by increasing the surface area of the trench bottom. This is done by adjusting the geometry to make the trench shallow and broad, rather than deep and narrow. Greater bottom surface area increases infiltration rates and provides more area and depth for soil filtering. In addition, broader trench bottoms reduce the risk of clogging at the soil/filter cloth interface by spreading infiltration over a wider area.

8. **Distance from Wells and Foundations.** The trench should be at least 100 feet of any drinking water supply well, and at least 10 feet down gradient and 100 feet up gradient from building foundations (Schueler, 1987).

9. **Drain Time.** The drain time should be between two and three days. The total volume of the trench should drain in 48 hours. The minimum drain time should be 24 hours.

10. **Backfill Material.** The backfill material in the trench should have a D_{50} sized between 1.5 and 3 inches and clay content should be limited to less than 30 percent. The porosity of the material should be between 0.3 and 0.4.

11. **Observation Well.** An observation well of 4 to 6 inches diameter PVC should be located in the center of the trench and the bottom should rest on a plate. The top should be capped. The water level should be measured after a storm event. If it has not completely drained in three days, some remedial work may need to be done.

12. **Overflow Berm.** A 2 to 3 inch emergency overflow berm on the downstream side of the trench serves a twofold purpose. First, it detains surface runoff and allows it to pond and infiltrate to the trench. The berm also promotes uniform sheet flow for runoff overflow.
REFERENCES

DESCRIPTION

Media filters are two-stage constructed treatment systems, including a pretreatment settling basin and a filter bed containing sand or other filter media. Various types of sand filter designs have been developed and implemented successfully in space-limited areas. The filters are not designed to treat the entire storm volume but rather the water quality volume (Chapter 9), that tends to contain higher pollutant levels. Sand filters can be designed so that they receive flow directly from the surface (via inlets or even as sheet flow directly onto the filter bed) or via storm drain pipes. They can be exposed to the surface or completely contained in underground pipe systems or vaults.

While there are various designs, most intermittent sand filters contain four basic components, as shown schematically in Figure PC-106A and discussed below:

1. **Diversion Structure.** Either incorporated into the filter itself or as a stand alone device, the diversion structure isolates the WQV and routes it to the filter. Larger volumes are bypassed directly to the storm drain system.
2. **Sedimentation Chamber.** Important to the long-term successful operation of any filtration system is the removal of large grained sediments prior to exposure to the filter media. The sedimentation chamber is typically integrated directly into the sand filter BMP but can also be a stand alone unit if space permits.
3. **Filter Media.** Typically consists of a 1-inch gravel layer over an 18 to 24 inch layer of washed sand. A layer of geotextile fabric can be placed between the gravel and sand layers.
4. **Underdrain System.** Below the filter media is a gravel bed, separated from the sand by a layer of geotextile fabric, in which is placed a series of perforated pipes. The treated runoff is routed out of the BMP to the storm sewer system or another BMP.

ADVANTAGES

1. May require less space than other treatment control BMPs and can be located underground.
2. Does not require continuous base flow.
3. Suitable for individual developments and small tributary areas up to 100 acres.
4. Does not require vegetation.
5. Useful in watersheds where concerns over groundwater quality or site conditions prevent use of infiltration.
7. Can be used in highly urbanized settings.
8. Can be designed for a variety of soils.
9. Ideal for aquifer regions.

LIMITATIONS

1. Given that the amount of available space can be a limitation that warrants the consideration of a sand filter BMP, designing one for a large drainage area where there is room for more conventional structures may not be practical.
2. Available hydraulic head to meet design criteria.
3. Requires frequent maintenance to prevent clogging.
4. Not effective at removing liquid and dissolved pollutants.
5. Severe clogging potential if exposed soil surfaces exist upstream.
6. Sand filters may need to be placed offline to protect it during extreme storm events.

**DESIGN CRITERIA**

1. **Treatment Rate.** Calculate the flow rate of stormwater to be mitigated by the media filtration according to the method in Chapter 9.

2. **Surface Area of the Filter.** The following equation is for a maximum filtration time of 24 hours:

   A. **Surface Systems or Vaults**
   
   \[ \text{Filter area (ft}^2\) = 3630 SuAH/K(D+H) \]

   Where:
   - \( Su \) = unit storage (inches-acre)
   - \( A \) = area in acres draining to facility
   - \( H \) = depth (ft) of the sand filter
   - \( D \) = average water depth (ft) over the filter taken to be one-half the difference between the top of the filter and the maximum water surface elevation
   - \( K \) = filter coefficient recommended as 3.5

   This equation is appropriate for filter media sized at a diameter of 0.02 to 0.04 inches. The filter area must be increased if a smaller media is used.

   B. **Underground Sandfilter Systems**

   a. Compute the required size of the sand filter bed surface area, \( AF \). The following equation is based on Darcy's law and is used to size the sand filter bed area:

   \[ AF \ (\text{ft}^2\) = 24(WQV)(df)/ [k (hf + df) tf] \]

   Where:
   - \( Af \) = sand filter bed surface area (ft²)
   - \( WQV \) = Water quality treatment volume (ft³)
   - \( df \) = sand filter bed depth (ft)
   - \( k \) = filter coefficient recommended as 3.5 (ft/day)
   - \( hf \) = average height of water above the sand bed (ft) = \( h_{max}/2 \)
   - \( h_{max} \) = elevation difference between the invert of the inlet pipe and the top of the sand filter bed (ft)
   - \( tf \) = time required for the runoff to filter through the sand bed (hr).
     (Typically 24 hr).

   Note: 24 in the equation is the 24hr/day constant.

   b. Choose a pipe size (diameter). The selection of pipe size should be based on site parameters such as: elevation of the runoff coming into the sand filter system, elevation of downstream connection to which the sand filter system outlet must tie into, and the minimum cover requirements for live loads. A minimum of 5' clearance should be provided between the top of the inner pipe wall and the top of the filter media for maintenance purpose. Use:

   \[ D = d + 5 \]

   Where:
   - \( D \) = pipe diameter (ft)
\[ \text{d} = \text{depth of sand filter and underdrain pipe media depth (ft)} \]
\[ = \text{dg} + \text{df} \]
\[ \text{dg} = \text{underdrain pipe media depth} = 0.67' \]
\[ \text{df} = \text{sand filter bed depth (ft): 1.5 to 2.0 feet} \]

c. Compute the sand filter width (based on the pipe geometry):

\[ W_f = 2 \left[ R^2 - (R - d)^2 \right]^{0.5} \]

Where:

\[ W_f = \text{filter width (ft)} \]
\[ R = \text{pipe radius (ft)} = D/2 \]

d. Compute the filter length:

\[ L_f = A_f/ W_f \]

Where:

\[ L_f = \text{filter length (ft)} \]

3. **Configuration**

A. Surface sand filter

Criteria for the settling basin.

a. Use a perforated riser pipe for the outlet.
b. Size the outlet orifice for a 24 hour drawdown
c. Energy dissipater at the inlet to the settling basin.
d. Trash rack at outlets to the filter.
e. Vegetate slopes to the extent possible.
f. Access ramp (4:1 or less) for maintenance vehicles.
g. One foot of freeboard.
h. Length to width ratio of at least 3:1 and preferably 5:1.
i. Sediment trap at inlet to reduce resuspension.

Criteria for the filter.

a. Use a flow spreader.
b. Use clean sand 0.02 to 0.04 inch diameter.
c. Some have placed geofabric on sand surface to facilitate maintenance.
d. Underdrains with:
   - Schedule 40 PVC.
   - 4 inch diameter.
   - 3/8 inch perforations placed around the pipe, with 6 inch space between each perforation cluster.
   - Maximum 10 foot spacing between laterals.
   - Minimum grade of 1/8 inch per foot.

B. Underground sand filter

Criteria for the settling tank (if required).

a. Use orifice and/or weir structure for the outlet.
b. Size the outlet orifice or weir for a 24 hour drawdown time
c. Provide access manhole for maintenance.
Criteria for the filter.

a. Use a flow spreader.
b. Use clean sand 0.02 to 0.04 inch diameter.
c. Some have placed geofabric on sand surface to facilitate maintenance.
d. Underdrains with:
   - Schedule 40 PVC.
   - 4 inch diameter
   - 3/8 inch perforations placed around the pipe, with 6 inch space between each perforation cluster.
e. Provide access manhole for maintenance.

DESCRIPTION

Storm drain inserts can be a variety of devices that are used in storm drain conveyance systems to reduce pollutant loadings in stormwater runoff. Most storm drain inserts reduce oil and grease, debris, and suspended solids through gravity, centrifugal force, or other methods. BMPs such as these can be particularly useful in areas susceptible to spills of petroleum products, such as gas stations. Figure PC-107A illustrates one of many different types of storm drain inserts. Trapped sediments and floatable oils must be pumped out regularly to maintain the effectiveness of the units.

ADVANTAGES

1. Prefabricated for different standard storm drain designs.
2. Require minimal space to install.

LIMITATIONS

1. Some devices may be vulnerable to accumulated sediments being resuspended during heavy storms.
2. Can only handle limited amounts of sediment and debris.
3. Maintenance and inspection of storm drain inserts are required before and after each rainfall event.
4. High maintenance costs.
5. Hydraulic losses.

DESIGN CRITERIA

1. Calculate the minimum flow rate to be mitigated by the storm drain insert using the methods in Chapter 9.
2. Select unit which meets 80% TSS removal for design flow rate.
3. Provide an overflow to bypass flows greater than the water quality treatment rate.

Figure PC-107A
Typical Storm Insert Schematic (SUSMP, 2002)
DESCRIPTION

Vegetated filter strips, also known as vegetated buffer strips, are vegetated sections of land similar to vegetated swales, except they are essentially flat with low slopes, and are designed only to accept runoff overland sheet flow (Schueler, 1992). They may appear in any vegetated form from grassland to forest, and are designed to intercept upstream flow, lower flow velocity, and spread water out as sheet flow (Schueler, 1992). The dense vegetative cover facilitates conventional pollutant removal through detention, filtration by vegetation, and infiltration into soil (Yu and Kaighn, 1992). Wooded and grass filter strips have slightly higher removal rates. Dissolved nutrient removal for either type of vegetative cover is usually poor, however wooded strips show slightly higher removal due to increased retention and sequestration by the plant community (Florida Department of Transportation, 1994).

Although an inexpensive control measure, vegetated filter strips are most useful in contributing watershed areas where peak runoff velocities are low, as they are unable to treat the high flow velocities typically associated with high impervious cover (Barret, et al., 1993). Similar to vegetated swales, filter strips can last for 10 to 20 years with proper conditions and regular maintenance. Life expectancy is significantly diminished if uniform sheet flow and dense vegetation are not maintained. Figures PC-108A and PC-108B illustrate a typical Buffer Strip and its schematic.

ADVANTAGES

1. Lowers runoff velocity (Schueler, 1987).
2. Slightly reduces runoff volume (Schueler, 1987).
3. Slightly reduces watershed imperviousness (Schueler, 1987).
4. Slightly contributes to groundwater recharge (Schueler, 1987).
5. Aesthetic benefit of vegetated “open spaces” (Colorado Department of Transportation, 1992).
6. Preserves the character of riparian zones, prevents erosion along streambanks, and provides excellent urban wildlife habitat (Schueler, 1992).

LIMITATIONS

1. Filter strips cannot treat high velocity flows, and do not provide enough storage or infiltration to effectively reduce peak discharges to predevelopment levels for design storms (Schueler, 1992). This lack of quantity control dictates use in rural or low density development.
2. Requires slope less than 5%.
3. Requires low to fair permeability of natural subsoil.
4. Large land requirement.
5. Often concentrates water, which significantly reduces effectiveness.
6. Pollutant removal is unreliable in urban settings.

DESIGN CRITERIA

1. Successful performance of filter strips relies heavily on maintaining shallow unconcentrated flow (Colorado Department of Transportation, 1992). To avoid flow channelization and maintain performance, a filter strip should:
   a. Be equipped with a level spreading device for even distribution of runoff,
   b. Contain dense vegetation with a mix of erosion resistant, soil binding species,
   c. Be graded to a uniform, even and relatively low slope,
Laterally traverse the contributing runoff area (Schueler, 1987),

The area to be used for the strip should be free of gullies or rills that can concentrate overland flow (Schueler, 1987),

Filters strip should be placed 3 to 4 feet from edge of pavement to accommodate a vegetation free zone (Washington State Department of Transportation, 1995). The top edge of the filter strip along the pavement should be designed to avoid the situation where runoff would travel along the top of the filter strip, rather than through it. Dilhalla, et al., (1986) suggest that berms be placed at 50 to 100 feet intervals perpendicular to the top edge of the strip to prevent runoff from bypassing it (as cited in Washington State Department of Transportation, 1995),

Top edge of the filter strip should follow the same elevation contour. If a section of the edge of the strip dips below the contour, runoff will tend to form a channel toward the low spot,

Filter strips should be landscaped after other portions of the project are completed (Washington State Department of Transportation, 1995). However, level spreaders and strips used as sediment control measures during the construction phase can be converted to permanent controls if they can be regraded and reseeded to the top edge of the strip.

2. Filter strips can be used on an up gradient from watercourses, wetlands, or other water bodies, along toes and tops of slopes, and at outlets of other stormwater management structures (Boutiette and Duerring, 1994). They should be incorporated into street drainage and master drainage planning (Urbonas, 1992). The most important criteria for selection and use of this BMP are soils, space, and slope, where:

a. **Soils and moisture are adequate to grow relatively dense vegetative stands.** Underlying soils should be of low permeability so that the majority of the applied water discharges as surface runoff. The range of desirable permeability is between 0.06 to 0.6 inches/hour (Horner, 1985). Common soil textural classes are clay, clay loam, and silty clay. The presence of clay and organic matter in soils improves the ability of filter strips to remove pollutants from the surface runoff (Schueler, 1992). Greater removal of soluble pollutants can be achieved where the water table is within 3 feet of the surface (i.e., within the root zone) (Schueler, 1992). Filter strips function most effectively where the climate permits year-round dense vegetation.

b. **Sufficient space is available.** Because filter strip effectiveness depends on having an evenly distributed sheet flow, the size of the contributing area and the associated volume runoff have to be limited (Urbonas, 1992). To prevent concentrated flows from forming, it is advisable to have each filter strip serve a contributing area of five acres or less (Schueler, 1987). When used alone, filter strip application is in areas where impervious cover is low to moderate and where there are small fluctuations in peak flow.

c. **Longitudinal slope is five percent or less.** When filter strips are used on steep or unstable slopes, the formation of rills and gullies can disrupt sheet flow (Urbonas, 1992). As a result filter strips will not function at all on slopes greater than 15 percent and may have reduced effectiveness on slopes between 6 to 15 percent.

3. The design should be based on the same methods detailed for swales. The referred geometry of a filter strip is rectangular, and this should be used when applying the design procedures of vegetated swales.

4. The following provisions apply specifically to filter strips (Horner, 1993):
a. Slopes should be no greater than 15 percent and should preferably be lower than 5 percent, and be uniform throughout the strip after final grading.

b. Hydraulic residence time normally no less than 9 minutes, and in no case less than 5 minutes.

c. Average velocity no greater than 0.9 feet/second.

d. Manning’s friction factor \( n \) of 0.02 should be used for grassed strips, \( n \) of 0.024 if strip is infrequently mowed, or a selected higher value if the strip is wooded.

e. The width should be no greater than that where a uniform flow distribution can be assured.

f. Average depth of flow (design depth) should be no more than 0.5 inches.

g. Hydraulic radius is taken to be equal to the design flow depth.

h. A minimum of 8 feet is recommended for filter strip width.

5. Filter strips function best with longitudinal slopes less than 10 percent, and ideally less than 5 percent. As filter strip length becomes shorter, slope becomes more influential. Therefore, when a minimum strip length of 20 feet is utilized, slopes should be graded as close to zero as drainage permits (Schueler, 1987). With steeper slopes, terracing through the use of landscape timber, concrete weirs, or other means may be required to maintain sheet flow.

6. Calculate the flow rate of stormwater to be mitigated by the vegetated filter strip using the Method outlined in Chapter 9.

7. Another design issue is runoff collection and distribution to the strip, and release to a transport system or receiving water (Horner, 1985). Flow spreader devices should be used to introduce the flow evenly to the filter strip (Urbonas, 1992). Concentrated flow needs to use a level spreader to evenly distribute flow onto a strip. There are many alternative spreader devices, with the main consideration being that the overland flow spreader be distributed equally across the strip. Level spreader options include porous pavement strips, stabilized turf strips, slotted curbing, rock-filled trench, concrete sills, or plastic-lined trench that acts as a small detention pond (Yu and Kaighn, 1992). The outflow and filter side lip of the spreader should have a zero slope to ensure even runoff distribution. The outflow and filter side lip of the spreader should have a zero slope to ensure even runoff distribution (Yu and Kaighn, 1992). Once in the filter strip, most runoff from significant events will not be infiltrated and will require a collection and conveyance system. Grass-lined swales are often used for this purpose and can provide another BMP level. A filter strip can also drain to a storm sewer or street gutter (Urbonas, 1992).

8. Filter strips should be constructed of dense, soil-binding deep-rooted water resistant plants. Dense turf is needed for grassed filter strips to promote sedimentation and entrapment, and to protect against erosion (Yu and Kaighn, 1992). Turf grass should be maintained to a blade height of 2 to 4 inches. Most engineered, sheet-flow systems are seeded with specific grasses. The grass species chosen should be appropriate for the climatic conditions and maintenance criteria for each project.

9. Trees and woody vegetation have been shown to increase infiltration and improve performance of filter strips. Trees and shrubs provide many stormwater management benefits by intercepting some rainfall before it reaches the ground, and improving infiltration and retention through the presence of a spongy, organic layer of materials that accumulates underneath the plants (Schueler, 1987). As discussed previously in this section, wooded strips have shown significant increases in pollutant removal over grass strips. Maintenance for wooded strips is virtually non-existent, another argument for using trees and shrubs. However, there are drawbacks to using woody plants. Since the density of the vegetation is not as great as a turf grass cover, wooded filter strips need additional length to accommodate more vegetation. In addition, shrub and tree trunks can cause uneven distribution of sheet flow, and increase the possibility for development of gullies and channels. Consequently, wooded strips require flatter slopes than a typical grass cover strip to ensure that the presence of heavier plant stems will not facilitate channelization.

Typical Buffer Strip (SUSMP, 2002)

Figure PC-108B
Typical Buffer Strip Schematic (SUSMP, 2002)
DESCRIPTION

Vegetated swales are shallow vegetated channels to convey stormwater where pollutants are removed by filtration through grass and infiltration through soil. They look similar to, but are wider than, a ditch that is sized only to transport flow. They require shallow slopes and soils that drain well. Vegetated swale designs have achieved mixed performance in pollutant removal efficiency. Moderate removal rates have been reported for suspended solids and metals associated with particulates such as lead and zinc. Runoff waters are typically not detained long enough to effectively remove very fine suspended solids, and swales are generally unable to remove significant amounts of dissolved nutrients. Pollutant removal capability is related to channel dimensions, longitudinal slope, and type of vegetation. Optimum design of these components will increase contact time of runoff through the swale and improve pollutant removal rates. Vegetated swales are primarily stormwater conveyance systems. They can provide sufficient control under light to moderate runoff conditions, but their ability to control large storms is limited. Therefore, they are most applicable in low-to-moderate sloped areas as an alternative to ditches and curb and gutter drainage. Their performance diminishes sharply in highly urbanized settings. Vegetated swales are often used as a pretreatment measure for other downstream BMPs, particularly infiltration devices. Enhanced vegetative swales utilize check dams and wide depressions to increase runoff storage and promote greater settling of pollutants.

ADVANTAGES

1. Relatively easy to design, install and maintain.
2. Vegetated areas that would normally be included in the site layout, if designed for appropriate flow patterns, may be used as a vegetated swale.
3. Relatively inexpensive.
4. Vegetation is usually pleasing to residents.

LIMITATIONS

1. Irrigation may be necessary to maintain vegetative cover.
2. Potential for mosquito breeding areas.
3. Possibility of erosion and channelization over time.
4. Requires dry soils with good drainage and high infiltration rates for better pollutant removal.
5. Not appropriate for pollutants toxic to vegetation.
6. Large area requirements may make this BMP infeasible for some sites.
7. Used to serve sites less than 10 acres in size, with slopes no greater than 5 percent.
8. The seasonal high water table should be at least 2 feet below the surface.
9. Buildings should be at least 10 feet from the top of bank.
DESIGN CRITERIA

Several criteria should be kept in mind when beginning swale design. These provisions, presented below, have been developed through a series of evaluative research conducted on swale performance. Criteria for optimum swale performance (Horner, 1993)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Optimal Criteria</th>
<th>Minimum Criteria*</th>

</table>

Note: * Criteria at or below minimum values can be used when compensatory adjustments are made to the standard design. Specific guidance on implementing these adjustments will be discussed in the design section.

The procedures described below were set forth by Horner, and unless otherwise cited, are set forth in *Biofiltration for Stormwater Runoff Quality Control*, published in 1993. The following steps are recommended to be conducted in order to complete a swale design:

1. Determine the flow rate to the system.
2. Determine the slope of the system.
3. Select a swale shape (skip if filter strip design).
4. Determine required channel width.
5. Calculate the cross-sectional area of flow for the channel.
6. Calculate the velocity of channel flow.
7. Calculate swale length.
8. Select swale location based on the design parameters.
9. Select a vegetation cover for the swale.
10. Check for swale stability.

Recommended procedures for each task are discussed in detail below.

1. *Determine Flow Rate to the System.* Calculate the flow rate of stormwater to be mitigated by the vegetated swale using the methods outlined in Chapter 9. Runoff from larger events should be designed to bypass the swale; consideration must be given to the control of channel erosion and destruction of vegetation. A stability analysis for larger flows (up to the 100-yr 24-hour) must be performed. If the flow rate approaches or exceeds 1 ft/s, one or more of the design criteria above may be violated, and the swale system may not function correctly (Washington State Department of Transportation, 1995). Alternative measures to lower the design flow should be investigated. Possibilities include dividing the flow among several swales, installing detention to control release rate upstream, and reducing developed surface area to reduce runoff coefficient value and gain space for biofiltration (Horner, 1993).

2. *Determine the Slope of the System.* The slope of the swale will be somewhat dependent on where the swale is placed, but should be between the stated criteria of one and six percent.

3. *Select a Swale Shape.* Normally, swales are designed and constructed in a trapezoidal shape, although alternative designs can be parabolic, rectangular, and triangular. Trapezoidal cross-sections are preferred because of relatively wider vegetative areas and ease of maintenance (Khan, 1993). They also avoid the sharp corners present in V-shaped and rectangular swales, and offer better stability than the vertical walls of rectangular swales.
4. Determine Required Channel Width. Estimates for channel width for the selected shape can be obtained by applying Manning’s Equation:

\[ Q = \frac{1.486}{n} AR^{2/3} S^{1/2} \]

Where:
- \( Q \) = Flow (ft³/s).
- \( A \) = Cross-sectional area of flow (ft²).
- \( R_h \) = Hydraulic radius of flow cross section (ft).
- \( S \) = Longitudinal slope of biofilter (ft/ft).
- \( n \) = Manning's roughness coefficient.

A Manning's \( n \) value of 0.02 should be used for routine swales that will be mowed with some regularity. A Manning's \( n \) value of 0.024 should be used for swales that will be infrequently mowed. A higher \( n \) value can be selected if it is known that vegetation will be very dense (Khan, 1993).

Because the channel is wide, the hydraulic radius approaches the flow depth. Substituting the geometric equations for a trapezoidal channel into Manning’s equation, the bottom width (\( w_b \)) and the top width (\( w_t \)) for the trapezoidal swale can be computed using the following equations:

\[ w_b = \frac{Qn}{1.486y^{1.07}S^{0.5}} - Zy \quad \text{and} \quad w_t = w_b + 2Zy \]

Where:
- \( Q \) = Flow rate in ft³/s.
- \( n \) = Manning’s roughness coefficient
- \( y \) = Depth of flow.
- \( Z \) = The side slope in the form of \( Z:1 \).

Typically, the depth of flow in the channel (\( y \)) is set at 3 to 4 inches. Flow depth can also be determined by subtracting 2 inches from the expected grass height, if the grass type and the height it will be maintained is known. Values lower than 3 to 4 inches can be used, but doing so will increase the computed width of the swale (Washington State Department of Transportation, 1995).

Swale width computed should be between 2 to 8 feet. Relatively wide swales (those wider than 8 feet) are more susceptible to flow channelization and are less likely to have uniform sheet flow across the swale bottom for the entire swale length. The maximum width for swales is on the order of 10 feet, however widths greater than 8 feet should be evaluated to consider the effectiveness of the flow spreading design used and the likelihood of maintaining evenness in the swale bottom. Since length may be used to compensate for width reduction (and vice versa) so that area is maintained, the swale width can be arbitrarily set to 8 feet to continue with the analysis.

5. Calculate Cross-Sectional Area. Compute the cross-sectional area (\( A \)) for the swale.

6. Calculate the Velocity of the Channel Flow. Channel flow velocity (\( V \)) can be computed using the continuity equation

\[ V \text{ (ft/sec)} = \frac{Q \text{(cfs)}}{A \text{(ft²)}} \]
This velocity should be less than 0.9 ft/s, a velocity that was found to cause grasses to be flattened, reducing filtration. A velocity lower than this maximum value is recommended to achieve the 9-minute hydraulic residence time criterion, particularly in shorter swales (at V = 0.9 ft/s, a 485-ft swale is needed for a 9-min residence time and a 269-ft swale for a 5-min residence time).

If the value of V suggests that a longer swale will be needed than space permits, investigate how the design flow Q can be reduced, or increase flow depth (y) and/or swale width (wt) up to the maximum allowable values and repeat the analysis.

7. **Calculate Swale Length.** Compute the swale length (L) using the following equation:

\[ L = 60Vt_r \]

Where:
- \( L \) = length required to achieve residence time
- \( t_r \) = Hydraulic residence time (in minutes).
- \( V \) = velocity of channel flow (ft/sec)
- Use \( t_r = 9 \) min for this calculation.

If a swale length greater than the space will permit results, investigate how the design flow Q can be reduced. Increase flow depth (y) and/or swale width (wb) up to the maximum allowable values and repeat the analysis. If all of these possibilities are checked and space is still insufficient, t can be reduced, but to no less than 5 minutes. If the computation results in L less than 100 ft, set \( L = 100 \) ft and investigate possibilities in width reduction. This is possible through recalculting V at the 100-ft length, recomputing cross-sectional area, and ultimately adjusting the swale width wb using the appropriate equation.

8. **Select Swale Location.** Swale geometry should be maximized by the designer, using the above equations, and given the area to be utilized. If the location has not yet been chosen, it is advantageous to compute the required swale dimensions and then select a location where the calculated width and length will fit. If locations available cannot accommodate a linear swale, a wide-radius curved path can be used to gain length.

Sharp bends should be avoided to reduce erosion potential. Regardless of when and how site selection is performed, consideration should be given to the following site criteria:

* **Soil Type.** Soil characteristics in the swale bottom should be conducive to grass growth. Soils that contain large amounts of clay cause relatively low permeability and result in standing water, and may cause grass to die. Where the potential for leaching into groundwater exists, the swale bottom may need to be sealed with clay to protect from infiltration into the resource. Compacted soils will need to be tilled before seeding or planting. If topsoil is required to facilitate grass seeding and growth, use 6 inches of the following recommended topsoil mix: 50 to 80 percent sandy loam, 10 to 20 percent clay, and 10 to 20 percent composted organic matter (exclude animal waste).

* **Slope.** The natural slope of the potential location will determine the nature and amount of regrading, or if additional measures to reduce erosion and/or increase pollutant removal are required. Swales should be graded carefully to attain uniform longitudinal and lateral slopes and to eliminate high and low spots. If needed, grade control checks should be provided to maintain the computed longitudinal slope and limit maximum flow velocity (Urbonas, 1992).
Natural Vegetation. The presence and composition of existing vegetation can provide valuable information on soil and hydrology. If wetland vegetation is present, inundated conditions may exist at the site. The presence of larger plants, trees and shrubs, may provide additional stabilization along the swale slopes, but also may shade any grass cover established. Most grasses grow best in full sunlight, and prolonged shading should be avoided. It is preferable that vegetation species be native to the region of application, where establishment and survival have been demonstrated.

9. Select Vegetative Cover. A dense planting of grass provides the filtering mechanism responsible for water quality treatment in swales. In addition, grass has the ability to grow through thin deposits of sediment and sand, stabilizing the deposited sediment and preventing it from being resuspended in runoff waters. Few other herbaceous plant species provide the same density and surface per unit area. Grass is by far the most effective choice of plant material in swales, however not all grass species provide optimum vegetative cover for use in swale systems. Dense turf grasses are best for vegetative cover.

In areas of poor drainage, wetlands species can be planted for increased vegetative cover. Use wetland species that are finely divided like grass and relatively resilient. Invasive species, such as cattails, should be avoided to eliminate proliferation in the swale and downstream.

Woody or shrubby plantings can be used for landscaping on the edge of side slopes, but not in the swale treatment area. Trees and shrubs can provide some additional stabilization, but also mature and shade the grass. In addition, leaf or needle drop can contribute unwanted nutrients, create debris jams, or interfere with waterflow through the system. If landscape plantings are to be used, selection and planting processes should be carefully planned and carried out to avoid these potential problems.

10. Check Swale Stability. The stability check is performed for the combination of highest expected flow and least vegetation coverage and height. Stability is normally checked for flow rate (Q) for the 100-yr, 24-h storm unless runoff from larger such events will bypass the swale. Q can be determined using the same methods mentioned for the initial design storm computation. The maximum velocity (Vmax) in ft/s, that is permissible for the vegetation type, slope, and soil conditions should be obtained.

DESCRIPTION

IMPORTANT NOTE: The material presented in this fact sheet is intended to apply to a case where a wet pond is being utilized as a post-construction stormwater quality BMP only. When the pond is being designed as a multi-purpose facility acting both as a water quality BMP and a wet-bottom detention pond described in Chapter 300, several design features must be modified to accommodate both purposes and requirements. Minimum requirements for a wet-bottom detention pond stated in Chapter 300 must be met and supersede any conflicting requirements in this fact sheet when water quality BMP features are added to a wet-bottom detention pond.

The wet pond or retention pond is a facility which removes sediment, Biochemical Oxygen Demand (BOD), organic nutrients, and trace metals from stormwater runoff. This is accomplished by slowing down stormwater using an in-line permanent pool or pond effecting settling of pollutants. The wet pond is similar to a dry pond, except that a permanent volume of water is incorporated into the design. The drainage area should be such that an adequate base flow is maintained in the pond. Biological processes occurring in the permanent pond pool aid in reducing the amount of soluble nutrients present in the water, such as nitrate and orthophosphorus (Schueler, 1987).

The basic elements of a wet pond are shown below. A stabilized inlet prevents erosion at the entrance to the pond. It may be necessary to install energy dissipaters. The permanent pool is usually maintained at a depth between 3 and 8 ft. The shape of the pool can help improve the performance of the pond. Maximizing the distance between the inlet and outlet provides more time for mixing of the new runoff with the pond water and settling of pollutants. Overflow from the pond is released through outlet structures to discharge flows at various elevations and peak flow rates. The outfall channel should be protected to prevent erosion from occurring downstream of the outlet.

Soil conditions are important for the proper functioning of the wet pond. The pond is a permanent pool, and thus must be constructed such that the water must not be allowed to infiltrate from the permanent portion of the pool. It is difficult to form a pool in soils with high infiltration rates soon after construction. Eventually, however, deposition of silt at the bottom of the pond will help slow infiltration. If extremely permeable soils exist at the site (hydrologic soil group A or B), a geotextile or clay liner may be necessary. Typical components of a Wet Pond are illustrated in Figures PC-110A.

ADVANTAGES

1. Wet ponds have recreational and aesthetic benefits due to the incorporation of permanent pools in the design.
2. Wet ponds offer flood control benefits in addition to water quality benefits.
3. Wet ponds can be used to handle large drainage areas.
4. High pollutant removal efficiencies for sediment, total phosphorus, and total nitrogen are achievable when the volume of the permanent pool is at least three times the water quality volume (the volume to be treated).
5. A wet pond removes pollutants from water by both physical and biological processes, thus they are more effective at removing pollutants than extended/dry detention basins.
6. Creation of aquatic and terrestrial habitat.
LIMITATIONS

1. Wet ponds may be feasible for stormwater runoff in residential or commercial areas with a combined drainage area greater than 20 acres but no less than 10 acres.
2. An adequate source of water must be available to ensure a permanent pool throughout the entire year.
3. If the wet pond is not properly maintained or the pond becomes stagnant; floating debris, scum, algal blooms, unpleasant odors, and insects may appear.
4. Sediment removal is necessary every 5 to 10 years.
5. Heavy storms may cause mixing and subsequent re-suspension of solids.
6. Evaporation and lowering of the water level can cause concentrated levels of salt and algae to increase.
7. Cannot be placed on steep unstable slopes.
8. Embankment may be regulated as a dam by IDNR.

DESIGN CRITERIA

1. Hydrology. If the device will also be used for stormwater quantity control, it will be necessary to reduce the peak flows after development to the levels described in Chapter 6.
2. Volume. Calculate the volume of stormwater to be mitigated by the wet pond using the water quality volume calculations in Chapter 9. The volume of the permanent pool should be 3 times this water quality volume.
3. Pond Shape. The pond should be long and narrow and generally shaped such that it discourages “short-circuiting.” Short-circuiting occurs when storm flows bypass the pond and do not mix well with the pool. Short-circuiting can be discouraged by lengthening the pond or by installing baffles which slow water down and lengthen the distance between the inlet and outlet. A length to width ratio of no less than 2:1, with 4:1 being preferred, will help minimize short circuiting. Also, the pond should gradually expand from the inlet and gradually contract toward the outlet. Several examples of ponds shaped to reduce short-circuiting are shown below. [See Figure PC-110B]
4. Depth. The depth of the water quality pond is important in the design of the pond. If the pond is too shallow, sediment will be easily resuspended as a result of wind. Shallow ponds should not be used unless vegetation is adequate to stabilize the pond. If the pond is too deep, safety considerations emerge and stratification may occur, possibly causing anoxic conditions near the bottom of the pond. If the pond becomes anoxic, pollutants adsorbed to the bottom sediments may be released back to the water column. The average depth should be 3 to 6 ft, and depths of more than 8 ft should be avoided (Schueler, 1987). A littoral zone of 6 to 18 inches deep that accounts for 25 to 50 percent of the permanent pool surface for plant growth along the perimeter of the pool is recommended, the littoral shelf will also enhance safety.
5. Vegetation. Planting vegetation around the perimeter of the pond can have several advantages. Vegetation reduces erosion on both the side slopes and the shallow littoral areas. Vegetation located near the inlet to the pond can help trap sediments; algae growing on these plants can also filter soluble nutrients in the water column. Thicker, higher vegetation can also help hide any debris which may collect near the shoreline. Native turf-forming grasses or irrigated turf should be planted on sloped areas, and aquatic species should be planted on the littoral areas (Urbonas, et al., 1992). Vegetation can benefit wildlife and waterfowl by providing food and cover at the marsh fringe. A shallow, organic-rich marsh fringe provides an area which enables bacteria and other microorganisms to reduce organic matter and nutrients (Schueler, 1987).
6. Side Slopes. Gradual side slopes of a wet pond enhance safety and help prevent erosion and make it easier to establish dense vegetation. If vegetation cannot be established, the unvegetated banks will add to erosion and subsequently the sediment load. It is recommended that side slopes be no greater than 3:1. If slopes are greater than this, riprap should be used to stabilize the banks (Schueler, 1987).
7. **Hydraulic Devices.** An outlet device, typically a riser-pipe barrel system, should be designed to release runoff in excess of the water quality volume and to control storm peaks. The outlet device should still function properly when partial clogging occurs. Plans should provide details on all culverts, risers, and spillways. Calculations should depict inflow, storage, and outflow characteristics of the design. Some frequently used design details for extending detention times in wet ponds are shown and described below (Schueler, 1987). [See Figure PC-110C]

   a. **Slotted Standpipe from Low-Flow Orifice, Inlet Control (dry pond, shallow wet pond, or shallow marsh).** An “L”-shaped PVC pipe is attached to the low-flow orifice. An orifice plate is located within the PVC pipe which internally controls the release rate. Slots or perforations are all spaced vertically above the orifice plate, so that sediment deposited around the standpipe will not impede the supply of water to the orifice plate.

   b. **Negatively Sloped Pipe from River (wet ponds or shallow marshes)** This design was developed to allow for extended detention in wet ponds. The release rate is governed merely by the size of the pipe. The risk of clogging is largely eliminated by locating the opening of the pipe at least 1 ft below the water surface where it is away from floatable debris. Also, the negative slope of the pipe reduces the chance that debris will be pulled into the opening by suction. As a final defense against clogging, the orifice can be protected by wire mesh.

   c. **Hooded Riser (wet ponds).** In this design, the extended detention orifice is located on the face of the riser near the top of the permanent pool elevation. The orifice is protected by wire mesh and a hood, which prevents floatable debris from clogging the orifice.

8. **Inlet and Outlet Protection.** The inlet pipe should discharge at or below the water surface of the permanent pool. If it is above the pool, an outlet energy dissipater will protect the banks and side slopes of the pond to avoid erosion. The stream channel just downstream of the pond outlet should be protected from scouring by placing riprap along the channel. Also, the slope of the outlet channel should be close to 0.5 percent. Riprap between 18 and 30 inches should be used. If the outlet pipe is less than 24 inches, 9 to 12 inches riprap may be used. Stillings basins may also be installed to reduce flow velocities at the outfall (Schueler, 1987).

9. **Forebay.** A forebay may be installed as part of the wet pond to capture sand and gravel sediment. The forebay should be easily accessible for dredging out the sediment when necessary and access to the forebay for equipment should be provided. The forebay volume should typically be 5 to 10 percent of the water quality volume. If there are multiple inlets to the detention facility, each forebay should be sized based on the portion of water quality volume attributed to the particular inlet.

10. **Emptying Time.** A 12 to 48 hour emptying time may be used for the water quality volume above the permanent pool (Urbonas, et al., 1992).

11. **Freeboard.** The pond embankment should have at least 1 ft of freeboard above the emergency spillway crest elevation (Schueler, 1987).
